KAPSEALS DILANTIN SODIUM^{*}

DILANTIN SODIUM (sodium 5,5-diphenylhydantoinate), an anticonvulsant with little or no hypnotic effect, is supplied for the treatment of epileptics not responsive to other medication. Extensive clinical use indicates that Dilantin Sodium will prevent, or greatly decrease the frequency and severity of, convulsive seizures in a majority of epileptics. However, since the significance of observed reactions to Dilantin Sodium is not fully established, patients receiving the drug should be closely observed.

LIBRARY,

Dilantin Sodium is accepted by the Council on Pharmacy and Chemistry of the American Medical Association for inclusion in New and Not Official Remedies...

Price of 100

^{*} The name 'Dilantin' Sodium designates the sodium salt of diphenyl hydantoin. 'Dilantin' Sodium was formerly known as 'Dilantin,' a term now designating the basic substance, diphenyl hydantoin. Dilantin Sodium is available as 0.1 Gram (1½-grains) and 0.03 Gram (½-grain) Kapseals, in bottles of 100, 500 and 1000.

The American Way Acc. 8:12-61

"The best program for medicine should be the product of the best minds of the American people. I propose that it be written by physicians, and when approved by organized medicine that it be submitted to the Congress. I believe that we should try to find an American Way—built upon the sound foundations of American experience."

NATHAN B. VAN ETEN, M.D.,
President-elect, American Medical Association

The New Year

Even in America the New Year has some of the aspects of a fearful question mark. Can this country remain unsinged by the flames of war so rapidly sweeping Europe and Asia? And if it does, what social and economic price must it pay for peace?

These questions have special implications for physicians. War makes tremendous and unpredictable demands on medical skill. Man's instruments of destruction do not behave in the relatively orderly manner of pathogenic bacteria. The latter pursue a more or less certain course in accord with the laws of their nature. The wounds inflicted in battle are fit offspring of the anarchy and horror which are war.

Besides a vast amount of horrible trauma, war almost always brings epidemic disease in its train. The breakdown of sanitary conditions at the front, the assemblage of vast numbers of men in limited quarters, exposure, inadequate diet, anxiety, all contribute to a weakening of the normal resistance to disease.

It is the hope of everyone that this country will remain out of war. Nevertheless our medical resources must be prepared to cope with the fruits of war. Even if we escape the direct trauma of battle, we cannot hope to remain immune to possible outbreaks of disease, like the influenza epidemic which swept the country in 1918.

Apart from questions rising directly from the war, however, the profession has many grave problems to face at the outset of 1940. Social and economic conditions are changing, and the traditional pattern of medical practice must be adapted to the new times without sacrifice of essential values. This requires a discriminating, determined attitude toward medicosocial legislation, with ready adoption of desirable reforms and firm resistance to changes threatening the standards and independence of medical practice. If we desire to prevent compulsory insurance under bureaucratic control, we must bend our efforts to make voluntary medical expense indemnity insurance work. If we desire to escape political domination, we must assume an attitude of constructive leadership on all questions pertaining to the public health.

Medicine's position at the outset of 1940 is difficult but by no means desperate. Reactionary opposition to beneficial change has been routed within and without the profession by the aroused social conscience of the nation. Russia's recent course has given pause to the advocates of authoritarian state control of medicine or anything else. The middle road, always the highway of civilized progress, is no longer despised. Let us follow it—to a Happy New Year.

On the March

Voluntary medical expense indemnity insurance is on the march in New York State. The first permit to operate a nonprofit plan has been granted to a Utica group which will serve twelve upstate counties with the cooperation of over five hundred physicians. A New York City corporation has applied for a permit to operate in the southeastern area. In the western end of the state a Buffalo group has launched a similar company.

There are definite statutory requirements which the organizers of such plans must bear in mind. In order to obtain a permit it is necessary to satisfy both the welfare and the insurance department. The former has ruled that an acceptable plan must be open to the participation of all reputable practitioners in the territory to be served and that the subscriber shall have free choice of physician subject to the latter's consent.

On the subject of management, state regulations are explicit. At least one-third of the directors shall be physicians and at least another third laymen. Even in medically sponsored plans this gives the public a substantial voice. All directors must be of such experience and standing as to guarantee their ability to administer the corporation's affairs in the best interests of all concerned.

Apart from strictly legal requirements there are several important considerations which should govern the organization of any plan for

voluntary nonprofit medical expense indemnity insurance. In the interests of responsible administration it is advisable for all groups seeking permits to have the approval of the State Medical Society and to be under trustworthy medical control in all essential respects.

The financial aspects of this type of insurance will have to be resolved by experience. It is obvious that premiums must be as low as possible to attract small wage-earners, the class it is desired to aid. At the same time they must be sufficient to permit reasonable compensation for participating physicians. If medical fees are inadequate, competent practitioners will be unwilling to cooperate. The current schedule for Workmen's Compensation has been proposed as a start.

In this type of insurance it is often feasible to dispense with preliminary medical examinations. Instead, a waiting period is set for disabilities resulting from pregnancy, malignancy, and comparable conditions.

Where administrative costs threaten to mount excessively, there may be a "ten-dollar-deductible" provision to eliminate the large volume of minor claims for sums which are not ordinarily a burden on the individual. In weighing the advisability of such a provision, the company should consider whether it would be likely to discourage early recourse to medical care.

The success of voluntary nonprofit medical expense indemnity insurance will go far to determine the future of private medical practice in this country. It is therefore of the utmost importance that such plans be in responsible hands and receive the cooperation of all reputable physicians.

Prevention of Silicosis

The interest of industrial hygienists has recently been aroused by the report of Denny, *et al.*,¹ that the inhalation of powdered metallic aluminum prevents silicosis. From experimental evidence, it appears that the toxicity of silica comes from that portion which is in the dispersed colloidal form and this can be inactivated by aluminum when the latter is in close association with quartz in the body cells.

Rabbits, which were exposed to quartz dust alone, all developed silicosis within a period of seven months. On the other hand, where the quartz dust was mixed with metallic aluminum powder in a concentration of 1 per cent, no animals showed any evidence of silicosis up to periods of seventeen and one-half months. For the prevention of the disease, Denny and his co-workers suggest that the aluminum dust should be below 5 microns in particle size and be free from grease. The dust should preferably be uniformly mixed with the silica dust,

¹ Denny J J *et al.* *Canad M A J* 40 No 3 (March) 1939

but will also be effective if inhaled each day independently. In itself, aluminum dust showed no effect on the health of the animals, and no toxicity or tissue damage.

Metallic aluminum in the tissues is converted into hydrated alumina which, by flocculation, by the adsorption of silica from solution, and by covering the quartz particle with an insoluble and impermeable coating, is able to reduce the toxicity of quartz in the tissues.

Problem of the Arthritic

For a considerable period of time, the dominant conception concerning arthritis was that it was solely the result of focal infection. Such is no longer the case. Intense investigation of the arthritic syndrome has made it apparent that there are certain physiologic deviations elsewhere in the body which are as important (if not more so) as the existence of an infectious focus in the production and course of rheumatoid arthritis. Pemberton's address before the American Rheumatism Association in May of this year¹ is an illuminating discussion of the considerations which must be evaluated in the treatment of arthritis. His pertinent remarks are all the more valuable because of the current interest in gold therapy for this condition, the most recent report being that of Soskin, Spanbock, and Kling.²

"The future may hold some single remedial agency which will reach to or near the heart of the oak but we are not yet in possession of it. Perhaps gold will prove as valuable to the patient in his body as it has proved to be in his pockets. *The somatic substrate of the arthritic subject, however, may not be so easily altered and usually needs a different approach.*"¹ [Italics ours.]

Since the care of arthritics is largely in the hands of the general practitioner, he cannot be blamed very much if, from the lack of co-ordination in the study of this disease, "he turns from academic negativism to the samples sent him by a drug house." The bacteriologist has his point of view, the pathologist considers only what the microscope reveals to him. But patients want relief from pain and from the incapacity to perform their daily tasks. At the present time, therefore, in the treatment of arthritis, the doctor must know how "to utilize the components of rest, to stimulate here and sedate there, to appreciate the significance of deficiencies or surfeits, to recognize and correct them, to discover an infection or other morbid nidus, to understand whether and when to remove it, to adjust his somatic and local mechanisms, in sum, to equilibrate the arthritic and treat him as few sufferers from other diseases are treated."

The Annual Meeting

The new year is here The outstanding medical event of the year for us is our annual convocation This year it will be held during the week of May 6 at the Waldorf-Astoria Hotel in New York City It is too early as yet to announce the program of events, but it is not too early to reserve the dates

The hotel has arranged special rates, the program will be unusually attractive, and the social events will also be a feature of this meeting

At this time we are directing attention to this coming event, so that you may arrange to come to New York and participate

Current Comment

"Good medical care has always been and always will be an individual service involving a close, personal confidential relationship between the patient and the physician of his choice and in the presence of such a relationship, it seldom if ever happens that the patient lets the doctor down in the matter of remuneration"—The October 14th issue of the *Weekly Roster and Medical Digest* discusses "Physicians' Remuneration" at some length, and brings out this point

"It is proper for a practicing physician to ask, 'What definite advantages may I expect from membership in the County Medical Society?'"

"Physicians can protect their professional rights and privileges only through organization and united effort. It is groups and blocs rather than individuals which mould public opinion And it is groups and blocs which can exert the most influence in legislative halls The first great reason for membership in the County Medical Society therefore may be said to be self-preservation, the preservation of the private practice of medicine through united effort

"Organized medicine is able to investigate and expose abuses in the field of health care Many quacks and charlatans have been exposed by the American Medical Association This confers two direct benefits upon every ethical practitioner It protects him from the com-

petition of the unscrupulous, and it protects the profession of medicine from degenerating to a point where the public would insist that government step in to remedy the abuses

"During the past decade the practice of medicine, as it has been known in the past and as we know it, has been threatened by those who would change the practice to a system which has been tried in foreign countries without any great success, and that is the reason I beg of you

to keep our organization strong and ask that each individual cooperate to his utmost because the battle is still before us We have merely won a few minor skirmishes to date and have kept the opposition from completely regimenting the profession

"Never before may the County Society, under the proper leadership, serve as a better influence for good through its public relations committee Let me plead for a solidarity of medical thought and action, for in spite of the fact that each County Society may have its own different problems and difficulties and may be forced to think and act differently on the same problems, the need for a unified profession has never been so important as it is today

"We have reached the point of time when the affairs or course of action of medicine must go on or be modified or terminated This is the decisive mo-

ment—it may be the turning point. We are now in a state in which a decisive change one way or the other is impending. What are you going to do about it? *It is in your hands!*”—Extremely pertinent remarks from an address by David W Thomas, M D, President of the Medical Society of the State of Pennsylvania, on “The Value of Medical Organization.”

“If the child and parent can be taught first, the value of good health, second, the need for medical care to conserve good health, the third, how to find and how to secure the medical care he needs, we are engaging upon a long-range health education program which will not only be of greater value to the child when he grows up, but which must in the meantime serve

to educate the parents and the rest of the community.”—From the September issue of the *Nassau Medical News* comes this sound suggestion.

“For my part I am still unconvinced that the family doctor is an anachronism. I still want somebody to save me from unsuitable or excessive specialist advice. I need someone to coordinate the findings of specialists and discount them if necessary, and above all I want someone who is willing to talk to me, at length, about my migraine, my little boy's delinquencies, my wife's recent strangeness, my baby's inoculation, and my daughter's desire to marry a man with asthma.”—The *Lancet* a short time ago carried this morsel.

Prize Essays

The Merrit H. Cash Prize and the Lucien Howe Prize will be open for competition at the next Annual Meeting of the Medical Society of the State of New York, May 6, 1940.

The Lucien Howe Prize of \$100 will be presented for the best original contribution on some branch of surgery, preferably ophthalmology. The author need not be a member of the Medical Society of the State of New York.

The Merrit H. Cash Prize of \$100 will be given to the author of the best original essay on some medical or surgical subject. Competition is limited to the members of the Medical Society of the State of New York, who at the time of the competition are residents of New York State.

The following conditions must be observed:

Essays shall be typewritten or printed and the only means of identification of the author shall be a motto or other device. The essay shall be accompanied by a sealed envelope having on the outside the same motto or device and containing the name and address of the writer.

If the committee considers that no essay or contribution is worthy of the prize, it will not be awarded.

All essays must be presented not later than April 1, 1940, and sent to the Chairman of the Committee on Prize Essays of the Medical Society of the State of New York, 2 East 103rd Street, New York City.

EUGENE H. POOL, M D, Chairman, Committee on Prize Essays

SCIENTIFIC EXHIBIT

Application blanks are now available for space in the Scientific Exhibit at the Annual Meeting at New York City, May 6, 7, 8, 9, 1940. Attention is called to the fact that applications close on January 1. Blanks will be sent on request to Dr. William A. Krieger, Chairman, Committee on Scientific Exhibits, 103 Hooker Avenue, Poughkeepsie, New York.

GIANT FOLLICLE LYMPHOBLASTOMA

A Benign Variety of Lymphosarcoma

GEORGE BAEHR, M D , and PAUL KLEMPERER, M D , New York City

IT is no longer adequate to use the term lymphosarcoma to describe a malignant growth arising from lymphatic tissue without specifying the type. Of all the malignant neoplasms, those that are of lymphatic origin permit classification into several sharply defined varieties. This classification of the several forms of lymphosarcoma is not based merely upon certain variations in pathologic structure. Clinical recognition of each distinctive type is important because the several varieties present a different course, prognosis, and therapy.

Although lymphosarcoma usually arises either in the lymph nodes or in the lymphatic tissue of the gastrointestinal tract, it may occasionally develop in islands of lymphatic tissue which are to be encountered in almost any organ or tissue. It may at first remain localized to one lymph node or group of lymph nodes, or it may spread rapidly throughout the lymphatic system so that almost all the lymph nodes of the body may be involved more or less uniformly by the time the patient first presents himself to a physician for examination. In some instances it would seem as if the disease began multicentrically in many lymph nodes or simultaneously in all the lymph nodes of the body.

The well-known reticulum cell sarcoma of lymph nodes usually has its origin in one node, although it soon spreads to adjacent lymph nodes. Its characteristic cell type resembles an undifferentiated, rapidly multiplying reticulum cell. The tumor usually grows with extraordinary rapidity so that death may at times occur within six or eight weeks after the onset. The normal structure of an involved lymph node is completely destroyed and

replaced by the uniformly cellular neoplasm which spreads wildly beyond the capsule of the gland into adjacent tissues. The cells are several times larger than lymphocytes, are irregular in shape and commonly present mitotic figures. Aside from the extraordinary rapidity of its clinical course, the reticulum cell sarcoma of lymph nodes is characterized by its relative resistance to x-ray therapy. The prognosis is usually hopeless.

As a contrast to the extremely malignant reticulum cell variety of lymphosarcoma, we now wish to report a benign variety which we have described under the term follicular lymphoblastoma.^{1,2} The clinical course of this condition is usually so insidious and prolonged and its clinical picture is so benign that we failed at first to recognize its essential neoplastic character. In its early stages it may present some difficulty in differentiation from simple hyperplasia of lymph nodes. In our first reports of this condition (1925 and 1927) we therefore erroneously termed it "Giant Lymph Follicle Hyperplasia" and "Malignant Lymph Follicle Hyperplasia of Lymph Nodes and Spleen."^{3,4} Symmers still holds that this condition begins as a lymph node hyperplasia.⁵

The disease is characterized by a painless swelling of lymph nodes and sometimes of the spleen. The patient usually presents himself for examination because enlarged nodes have been discovered either in one part of the body such as the cervical region or generalized throughout the body. If the lymphadenopathy is generalized, the spleen is found to be enlarged.

There are as a rule no subjective complaints, no weakness, fever, anemia, or

FIG. 1 Spleen in case of follicular lymphoblastoma showing huge lymph follicles

cachexia. The blood count is normal. In fact the patient seems to be otherwise entirely well. Lymphatic leukemia is at first suspected but is ruled out by the normal blood and bone-marrow examination. Hodgkin's disease is eliminated by the absence of fever but conclusively only by biopsy and microscopic examination of a lymph node.

The first two illustrations (Figs. 1 and 2) are microphotographs of the first case which one of us (G. B.) observed in 1914. The enlargement of the lymph nodes is seen to be due to the presence of an enormous number of huge lymphoid follicles, which are often grossly visible on the cut surface or can be seen with a hand lens.

Microscopically, the lymph nodes are occupied almost wholly by the overgrown lymphoid follicles which crowd one another because of their huge size, so as to compress and obliterate the intervening lymph sinuses. The follicles are at least four or five times the normal size and present the microscopic appearance of enormously enlarged germinal centers.

Upon higher magnification, this appearance is seen to be due to the fact that they are composed of typical lymphoblasts or prelymphoblasts with large, pale-staining, reticulated nuclei, some of which show mitotic figures. The periphery of each follicle is generally clearly outlined by a narrow zone of small, mature lymphocytes with deeply staining nuclei.

In the early stages of the disease when the nodes are still discrete, a careful search of the capsule will usually reveal some tendency to invasion. In the later stages of the disease, sometimes years after the onset, the process may become more malignant and may then spread beyond the confines of the capsule into adjacent structures, and yet the same tendency to form follicles is still preserved.

Enlargement of the spleen is present in most cases, but by no means in all. It may occasionally be so large as to reach to the iliac crest and may weigh more than 1,800 Gm. The cut surface of the organ is striking, for it is thickly studded with large malpighian bodies which

FIG 2 Lymph node showing large follicles and between them the compressed lymphoid tissue

swell up above the cut surface, some as large as barley grains

The giant follicles are much more numerous than in the normal spleen and lie in close proximity to one another. Microscopically, they are even larger than in the lymph nodes and resemble giant germinal centers. Their number proves beyond question that the condition cannot be due to simple hyperplasia but that it represents a new formation of giant follicle-like structures.

Aside from the involvement of lymph nodes, either regionally or generalized, and of the spleen, the tumors may appear in parts of the body which ordinarily contain little lymphoid tissue, such as the fat of the orbit, the lachrymal gland, the breast, the loose connective tissue of the pelvis, and the subcutaneous fat. Nodules of tumor tissue excised from these locations show the same histologic picture of characteristic follicle formation. In one instance, the bone marrow was involved resulting in a pathologic fracture of the femur eleven years after the onset.

It is peculiar that thus far we have never observed involvement of the tonsil or of the lymphatic tissue of the gastrointestinal tract.

In many cases with generalized lymphadenopathy some part of the lymphatic system was more conspicuously involved and was responsible for the symptoms which first attracted attention. We have twice observed an exceptionally large mass of retroperitoneal nodes which caused partial pyloric obstruction by compression on the antral part of the stomach. Mediastinal lymph node enlargements may compress the trachea and the great vessels in the superior mediastinum.

A characteristic result of involvement of the mediastinal or abdominal lymph nodes is the occurrence of serous or even chylous effusions in the pleural or peritoneal cavity. This is due to compression of the lymph sinuses of the nodes by the enlarged lymph follicles, thereby interfering with the flow of lymph. Simple removal of the effusion by Potain aspiration or by trocar is always followed

by rapid reaccumulation of the fluid. Recurrence of the effusion is only prevented if the lymphatic swelling in the mediastinum or abdomen is reduced by means of roentgen-ray therapy and the lymph sinuses of the nodes again become permeable to the flow of lymph.

In 6 cases we observed the development of unilateral proptosis some time during the course of the disease. The protrusion of the eyeball was downward and outward. It was apparently caused by involvement of the orbital fat or of the lachrymal gland. In every instance the protruded eye returned to its normal position after a course of roentgen-ray or radium therapy. In one case, proptosis of the opposite eye developed two years after the first, but also subsided after radiotherapy.

Roentgen-ray Therapy—Aside from its characteristic pathology and its relatively benign and prolonged clinical course, the most important feature of the disease is its extremely sensitive response to deep roentgen-ray therapy. The results are more prompt and are achieved with far smaller doses than with any other type of neoplasm. The contrast is striking even when compared with other types of lymphosarcoma.

The swollen lymph nodes and spleen usually melt away within a few weeks after a few exposures to 170 international roentgen units (one-fifth of an erythema dose). In spite of this fact, the patients must continue to be examined every few months for the rest of their life, for recurrences are apt to occur, often in lymph nodes distant from the original site, or enlarged nodes may appear in unusual parts of the body where lymphatic tissue is rarely encountered, such as the scalp, the orbit, or the subcutaneous tissue. These recurrences are usually equally susceptible to roentgen-ray therapy. In some instances, the intervals of freedom from recurrences have been as long as six years.

In this manner some patients may contrive to live out their normal span of life and ultimately succumb to another

disease. In other cases, roentgen therapy easily checks the primary process and successfully controls subsequent recurrences for a period of four to fifteen or more years after the onset. Again in other patients the neoplastic process ultimately changes its character, involves retroperitoneal and thoracic lymph nodes extensively and seems to become more malignant and roentgen resistant. Death then ensues as in other forms of lymphosarcoma. Even in these cases the prognosis and the clinical course of the disease is usually benign for the first few years and the condition is readily controllable with roentgen therapy during this period.

In its clinical picture—general lymphadenopathy and splenomegaly without fever, anemia, or cachexia, and in its responsiveness to roentgen therapy or radium—the disease resembles chronic lymphatic leukemia. However, the bone marrow is usually normal and no abnormal leukocytes are found in the blood stream. The differential diagnosis can also be made by the histologic picture of an excised lymph node. This is of special importance because in the terminal stage of the disease we have twice observed a marked increase in leukocytes and the appearance of lymphoblasts in the blood stream. If these two patients had been observed only in this terminal stage, the clinical picture could not have been easily differentiated from chronic lymphatic leukemia. The preceding course of the disease over a period of years with an absolutely normal blood picture and, above all, the characteristic histologic changes in the lymph node left no doubt of the diagnosis. These two experiences suggest that follicular lymphoblastoma may represent a borderline condition between lymphosarcoma and lymphatic leukemia, just as in its early stages the disease may seem to represent a transition between hyperplasia and lymphosarcoma. Our clinical and pathologic studies of a great many cases at various stages of the disease, from onset to autopsy years later, leave us in no doubt that the condition is a variety of lymphosarcoma.

Discussion

Dr John S Lawrence, *Rochester*—This presentation by Drs Baehr and Klemperer has been of particular interest to me. Anything that anyone can do to make diseases of the lymphoma group less confusing is highly desired. They have presented clear-cut findings which will enable us to separate this one rare condition from others that are included under the term lymphosarcoma.

It has been my good fortune to have seen recently a patient with this disorder. This patient, a man 51 years of age, was studied in the metabolism division of the Strong Memorial Hospital from March 4, 1938, to July 15, 1938, by Drs Samuel H Bassett, Nolan L Kaltreider, and Henry Keutmann. The nature of his disorder was not known at this time and the detailed studies which were made on him were carried out as a part of a study on edema, which was his presenting complaint. During this entire period of observation his serum protein values ranged between 3.0 and 3.5 Gm per cent with an A/G ratio of about 2. Restriction of salt and water did, however, cause a loss in weight of 22 kg in about thirty days without any change in the total protein values of the blood. There were no abnormal lymph nodes and the spleen was not palpable at this time.

In July, 1938, an exploratory laparotomy was done. Hard, rubbery lymph nodes were found at the root of the mesentery and around the common bile duct. Biopsy of the liver revealed normal tissue. That of a lymph node showed findings of chronic inflammation. Following

operation he was given 1,800 roentgens to 4 ports in the course of ten days. The effective dose was estimated as about 300 roentgens to each area. The serum protein began to rise soon after this and soon reached a normal level with disappearance of the tendency to become edematous.

In December, 1938, he had acute obstructive jaundice. At operation the gallbladder, which five months previously had contained no stones, was found to be filled with small calculi. The obstruction was thought to have been due to glands in the portal area and spontaneously was relieved in three to four weeks. Last month splenomegaly and an enlarged cervical node were noted. The cervical lymph node was removed on April 13, 1939. The findings were typical of those that have been given by Drs Baehr and Klemperer. This patient illustrates the tendency to develop fluid in the body cavities and the ability of the enlarged lymph nodes to cause compression, both of which tendencies have been emphasized by the authors. There is one striking finding, however, which they have not mentioned—the very low serum protein level which was relieved following irradiation. Considerable speculation has arisen as to the explanation for the hypoproteinemia. Loss of protein into the excess fluid in the peritoneal cavity and body tissues is invalidated as an explanation by the maintenance of hypoproteinemia after disappearance of the excess fluid. Some abnormality of the liver resulting in inability to manufacture serum proteins has been suggested but it is hard to see how irradiation could have corrected this. Still another possibility is that blockage of the lymphatic drainage prevented the absorption of some hypothetical substance that is necessary for the production of serum proteins. I hope Dr McCann, who was the first one to see this patient in our clinic, will comment on these findings. In closing, I would like to ask Dr Baehr if he has encountered hypoproteinemia in any of his cases.

RED-BLOODED YOUNG PEOPLE

A prime fascination of medicine is that it is a never-ending study. Merely not to forget what you have learned cannot keep you ready for the obligations of medicine. Without forgetting anything that you learn in medical school, soon as physicians, surgeons, specialists, etc., you will become hopelessly behind the times, unless you continue to study. Not forgetting will not keep you from rapidly losing out in medicine, what you may know soon is apt to be completely outmoded by new discovery. In your medical

school days, I dare say, this idea of a never-ending study did not seem such a joy. However, how dull a profession medicine would be if, in a four years' study in the medical school, you had learned all that was needed to practice the profession the remainder of your lifetime. That sort of a profession would not attract into it red-blooded young people.

A CLINICAL STUDY OF HYPNOTICS

Effect on Gross Sleep Movements, Length of Sleep, Blood Pressure, Respiratory Rate, and Pulse Rate

FRANK MEYERS, M D , Buffalo, EDWARD D COOK, M D , Buffalo, and ROBERT C PAGE, M D , Mount Vernon

(From the Medical Service of the Buffalo General Hospital)

THE nature of sleep has been studied repeatedly and exhaustively, yet we have only theories as to how this phenomenon occurs. In spite of the comprehensive work in this field which has been performed by Shepard,¹ Kleitman,² and Johnson,³ no uniformity of opinion exists.

The frequent occurrence of insomnia as a symptom has led to the use of hypnotics to a staggering degree. Hambourger,⁴ in a recent article on "A Study of the Promiscuous Use of the Barbiturates," reports that 1,219,000,000 grains of barbitol compounds were sold in the United States in the year 1936, a figure which, if broken down, would indicate that 2,200,000 therapeutic doses of these drugs were used daily. Hypnotic habit is rapidly reaching proportions comparable to the cathartic habit. The use of sleep-inducing drugs by the laity without medical supervision becomes an ever-increasing hazard. Hambourger states in his report that "the number of suicides by barbiturates has shown a definite upward trend during the past decade especially marked since 1933."

The family of hypnotics is increasing rapidly, each new member, supposedly, is a more admirable addition. In spite of the large number of hypnotic drugs in use today, very few have been subjected to adequately controlled clinical testing. Up until the present, objective experimental study has been conducted principally on animals. These experiments mainly consisted of the demonstration of the therapeutic index, i.e., the difference between the minimum amount necessary to produce anesthesia

and the minimum amount necessary to produce death. However, anesthesia in animals can hardly be compared to hypnosis in humans, for the reason that hypnosis in animals is very difficult to differentiate from anesthesia. It is first necessary to anesthetize the animal before a hypnotic action may be established. By this token, we are dealing with anesthetic doses of hypnotics in animals and are merely reasoning by analogy as to their hypnotic effect on man.

Sleep is primarily a cerebral function which is difficult at best to measure, but it is accompanied by several phenomena which can be determined accurately. These phenomena are (1) length of sleep, (2) time of onset of sleep, (3) number of gross movements made during sleep, (4) changes in pulse rate, (5) changes in respiratory rate, (6) changes in blood pressure. The influence of therapeutic doses of hypnotics upon these associated phenomena of sleep forms the basis of our study.

Outline of Experiment

Subjects for these experiments were chosen carefully. Only patients who were free from pain, and those who were not having treatment which might have influenced their sleep were selected for study. None of these patients received opiates or sedatives as part of their daytime treatment. The experiments were conducted in a room segregated from the large public ward in order that the subjects might be protected from noises. The subjects received their usual ward routine care during the day.

Read at the Annual Meeting of the Medical Society of the State of New York, Syracuse, April 26, 1939

From 9 00 P M to 8 00 A M, and longer when necessary, these patients were under constant observation by a nurse who was especially trained for this study. Two beds were used in this experiment, both were attached to actographs.

The device used to record sleep movements in our experiments consisted of a thin brass plate six inches in diameter, placed in the center of the bed under the patient's hips and resting on top of the mattress. This plate was connected by a string and pulley to a writing lever which recorded all the movements of the patients on a kymograph operated by an electric clock. The writing lever was so adjusted that any movement of an arm or leg would be recorded as a gross excursion on the drum. The electric clock was so timed that it took nine hours for the drum to make one complete revolution. Pulse rates were determined by palpation at the wrist, respiratory rates were directly observed and both were recorded at half-hourly intervals, the blood pressure was recorded on a mercury manometer by auscultation at hourly intervals. The subjects slept with a blood pressure cuff on their upper arm, just before the reading was taken the mercury manometer was attached and the cuff gently inflated. Rarely did this awaken the patient. The greatest decrease from the initial level at the onset of sleep which occurred during the night was used in recording our results. The onset of sleep was judged by the observer and recorded. At times it was difficult to estimate exactly when a patient fell asleep. The length of sleep was measured by the number of hours between the onset of sleep and full awakening.

The following drugs were used: a placebo, N-tolyl-butyl-ethyl-barbital, Neonol, a urea derivative,* sodium pentobarbital, and sodium amytal. Various doses within the therapeutic range were administered. These drugs were chosen because they are of the short-acting type. We avoided drugs which

* The urea derivative used was unsymmetrical ethyl-ethylphenylurea.

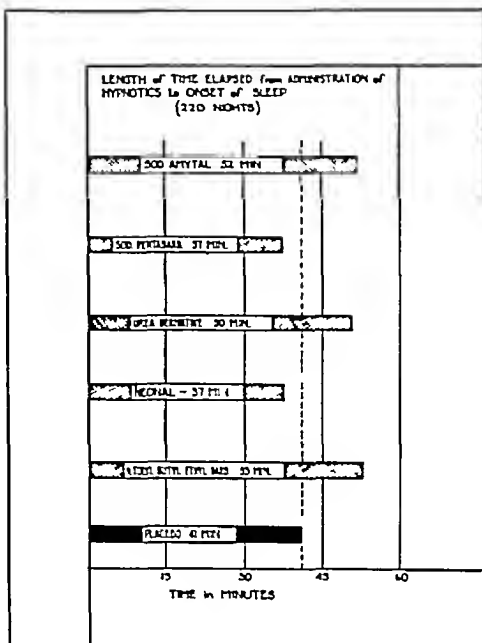

FIG 1

were slowly excreted because of the possibility of a cumulative effect. Each of these drugs was pressed into tablets, all having a similar appearance in order that the subjects would not know what medication they were receiving. We studied 12 patients—a total of 219 nights of observation. Each subject remained in the sleep room for a minimum of fourteen days and a maximum of twenty-six days. The patients received the placebos and the hypnotics in no definite order but each patient received the placebo at least four times during the course of study. We would point out, at this time, that the purpose of this experiment was not a comparative study of the various drugs used, but an observation, of this group as a whole, on the associated phenomena of sleep. It is also a method of clinical approach to the effectiveness of hypnotic drugs.

In the 219 observations on 12 patients given a drug and the time of onset of sleep recorded, it was found that sleep was not induced more rapidly by therapeutic doses of hypnotics. After the placebo, which was administered fifty-

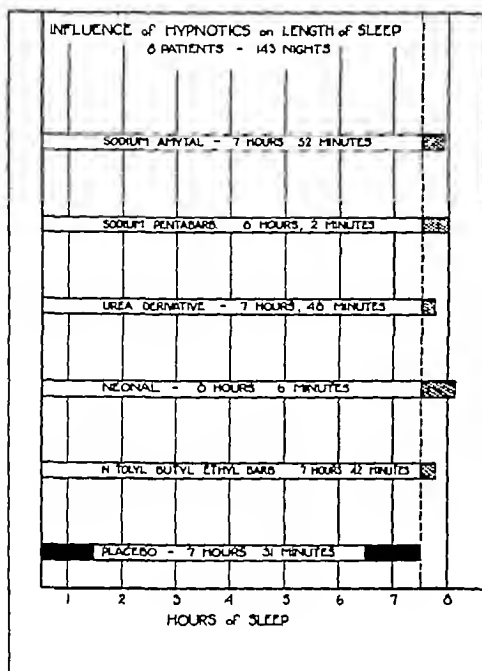

FIG 2

two times in this group, it was found that the average onset of sleep was forty-one minutes after taking the tablet, sodium pentobarbital and Neonal, studied for 25 and 38 nights, respectively, induced sleep four minutes earlier. With the other drugs, the onset of sleep was prolonged by an average of ten minutes.

TABLE A

Drug	Time Elapsed Before Onset of Sleep After Administration (Minutes)	Number of Times Administered
Placebo	41 1	52
Neonal	37 4	38
Sodium pentobarbital	37 4	25
Urea derivative	50 6	47
Sodium amyral	51 7	16
N-tolyl butyl-ethyl barbit	52 9	41

Of the 12 subjects studied, four were individuals with moderate cardiac decompensation. Since the findings in these four varied considerably from the other eight, they were considered separately.

The first group of eight consists of the patients with normal cardiovascular mechanisms—These patients slept slightly longer after hypnotics than they did after the placebo. The largest increase of 32.5

FIG 3

minutes occurred with Neonal, the smallest increase of eleven minutes occurred with N-tolyl-butyl-ethyl-barbital. The length of sleep was not increased to the degree one might reasonably expect following administration of these hypnotics.

TABLE B

Drug	Length of Sleep (Hours) (Minutes)	Increase in Minutes
Placebo	7 31	
Neonal	8 6	32.5
Sodium pentobarbital	8 2	28
Sodium amyral	7 52	21
Urea derivative	7 48	17
N-tolyl butyl-ethyl barbit	7 42	11

These drugs had but slight effect on the sleep pattern or gross movements. On a placebo the entire group averaged 36 movements per night. A decrease of sleep movements was produced by sodium pentobarbital and Neonal, each reducing sleep movements about 10 per cent. The other drugs increased sleep movements.

TABLE C

Drugs	Number of Sleep Movements per Night
Placebo	36 6
Sodium pentobarbital	30 2
Neonal	32 4
Urea derivative	37 2
Sodium amyral	38 2
N-tolyl butyl-ethyl barbit	38 5

Figures 4 and 5 are photographs of actograms on 2 patients, showing extreme individual differences of sleep patterns and how little hypnotics affected them.

MR. J. A.
DRUG: NEONAL 30MR. J. A.
DRUG: PLACEBO

FIG 4

The first actogram shows that this patient was a very quiet sleeper, making few movements during the entire period of sleep. On Neonal he made 14 gross movements, he slept nine hours, and fell asleep forty-five minutes after the drug was administered. This same subject, when a placebo was administered, made 17 gross movements during the night. He slept a total of eight hours and twenty minutes, the onset of sleep being the same as when Neonal was administered.

The second actogram shows the pattern of a patient who was very restless and who made frequent gross movements during the entire night. In the early morning hours just before this patient awakened, gross movements were made so frequently on the slowly revolving drum that many of them superimposed, and we were unable to count them accurately. With sodium amytal, he made 106 gross movements during the night, he slept nine hours and five minutes, and the onset of sleep occurred in thirty

MR. S. A.
DRUG: SODIUM AMYTAL 30MR. S. A.
DRUG: PLACEBO

FIG 5

FIG 6

FIG 7

minutes after administration of the drug. The actogram, after a placebo, showed very little deviation from that obtained with the drug. The number of gross movements was 101 during the night, the total time of sleep was nine hours and twenty minutes, and he fell asleep thirty minutes after the administration of the placebo.

Pulse Rate—It is accepted that normal sleep is accompanied by a drop in pulse rate. In this group of 8 subjects, the pulse rate at the onset of sleep averaged 83 beats per minute for a period of 143 nights. With the placebo medication the average greatest pulse rate drop was from 83 to 68 beats per minute, with the use of hypnotics a greater reduction in pulse rate was found.

TABLE D

Drug	Greatest Decrease from Initial Rate (No of Beats)	Percentage of Greatest Decrease from Initial Rate
Placebo	15	17.8
Sodium pentobarbital	20	24.3
Urea derivative	19.7	23.8
Neonal	19.3	23.3
N-tolyl-butyl-ethyl barbitol	17	20.5
Sodium amytal	16	19.3

Respiratory Rate—Respiratory rate, too, is known to be reduced in sleep. In our group of 8 patients with normal cardiovascular mechanisms, the average respiratory rate at the onset of sleep for 143 nights was 20 per minute. During normal sleep the average maximum fall in respiratory rate was from 20 to 16½.

or 17 per cent. Each of these drugs occasioned a further slight reduction in respiratory rate.

TABLE E

Drug	Greatest Fall from Initial Rate (No per Minute)	Percentage of Greatest Fall
Placebo	3.4	17
Sodium pentobarbital	5	25.2
Urea derivative	4.2	21.1
Neonal	4.1	20.5
Sodium amytal	3.9	19.9
N-tolyl butyl ethyl barbitol	3.5	17.5

Blood Pressure—All observers agree that there is a fall in both systolic and diastolic blood pressure during sleep of normal and hypertensive people. In our observations, the mean blood pressure of these 8 subjects, at the onset of sleep for a period of 143 nights, was 110 mm systolic and 72 mm diastolic. In normal sleep their average greatest drop in blood pressure was found to be 23 mm systolic and 13 mm diastolic. All

TABLE F

Drug	Average Greatest Fall from Initial Level (in Mm.)	Percentage of Greatest Fall
Placebo	23.4 systolic	21.3
	12.7 diastolic	17.2
Sodium pentobarbital	28.9	26.3
	18.3	25.5
Urea derivative	26.8	24.4
	15.9	22.1
Neonal	26.0	23.7
	16.7	23.3
Sodium amytal	25.7	23.4
	15.6	21.8
N-tolyl butyl ethyl barbitol	19.9	18.1
	10.3	14.1

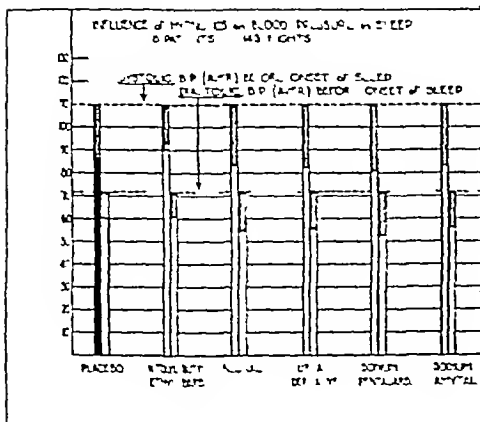

FIG 8

of the hypnotics used, with the exception of N-tolyl-butyl-ethyl-barbital, produced a further fall in blood pressure

Comment

Eight Subjects with Normal Cardiovascular Mechanisms—The hypnotics used produced a slight but consistent reduction in pulse and respiratory rates, and systolic and diastolic blood pressures. The length of sleep was increased by an average of only 21.5 minutes and no effect was produced on the sleep pattern or gross movements.

The second group consists of 4 patients with moderate congestive heart failure—In each instance hypnotics increased the length of sleep slightly. On the placebo the average length of sleep was seven hours and fifty-three minutes, the greatest increase of forty minutes occurred with sodium pentobarbital.

TABLE G

Drug	Length of Sleep (Hours) (Minutes)	Increase in Minutes Over Placebo
Placebo	7 53	
Sodium pentobarbital	8 33	40
N tollyl butyl-ethyl-barbital	8 13	20
Neonal	8 10	17
Urea derivative	8 6	13
Sodium amytal	8 3	10

In this group it was found that sleep was accompanied by a greater number of gross movements or marked restlessness

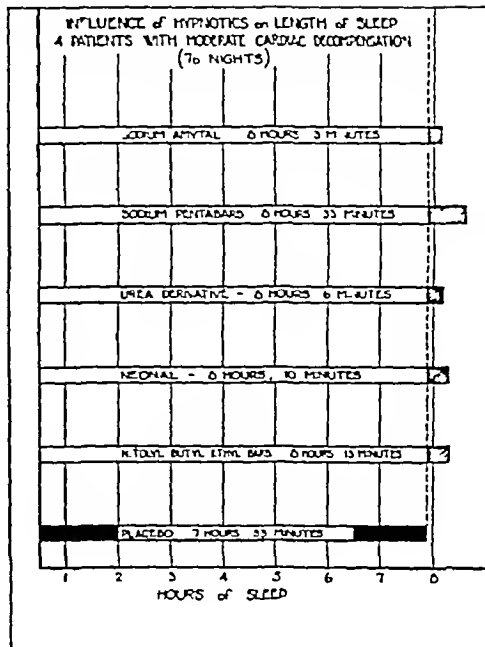

FIG 9

Following a placebo the average number of sleep movements was 54 per night. The subjects in this group averaged 18 more gross movements per night than those of the first group. Only sodium pentobarbital did not effect gross sleep movements, whereas the other hypnotics increased movements appreciably.

TABLE H

Drug	Average No. of Sleep Movements
Placebo	54
Sodium pentobarbital	53
Neonal	58.3
Urea derivative	61.3
Sodium amytal	67.3
N tollyl butyl-ethyl-barbital	68

Pulse Rate—The average pulse rate at the onset of sleep for this group, for a period of 76 nights, was 90 beats per minute. Without hypnotics the average greatest drop in pulse rate, was found to be 12.7 beats per minute lower than the initial rate. Slight further depression in the pulse rate was observed in two instances. Sodium pentobarbital and Neonal further depressed the normal drop. Under the influence of the

FIG 10

FIG 11

other three drugs, the pulse rate was not diminished beyond the point obtained by the placebo. In each instance, the hypnotics produced a fall of less magnitude than the fall in the normal group.

TABLE I

Drug	Average Greatest Drop from Initial Rate (Beats per Minute)	Average Percentage of Greatest Drop
Placebo	12.7	14.1
Sodium pentobarbital	10.7	18.6
Neonal	14.1	15.7
Urea derivative	12	13.4
Sodium amytal	11.9	13.3
N-tolyl butyl-ethyl-barbital	9.1	10.1

Respiratory Rate—In this group of 4 subjects, the respiratory rate for a period of 76 nights averaged 25 per minute at the onset of sleep. The average greatest respiratory rate drop after the administration of a placebo was from 25 to 21.7 per minute or 14.4 per cent. All the drugs, with the exception of N-tolyl-butyl-ethyl-barbital, further increased the fall in respiratory rate.

Blood Pressure—In this group the blood pressure changes were not as marked as in the subjects with normal cardiovascular mechanism. The mean blood pressure for 76 nights, at the onset of sleep, was found to be 113 mm systolic and 78 mm diastolic. Without medication, the greatest blood pressure drop averaged 15.2 mm systolic and 11 mm diastolic. There was a further depression

TABLE J

Drug	Average Greatest Fall in Resp. Rate (No. per Min.)	Percentage of Greatest Fall
Placebo	3.6	14.4
Urea derivative	4.7	19.1
Sodium pentobarbital	4.6	18.5
Neonal	4.4	17.9
Sodium amytal	3.5	14.1
N-tolyl butyl-ethyl-barbital	2.9	11.6

in the blood pressure under the influence of each of the drugs studied, the relationship of the systolic and diastolic pressures did not change.

TABLE K

Drug	Average Greatest Drop in Blood Pressure (in Mm.)	Percentage of Greatest Drop
Placebo	15.2 systolic	13.5
	11 diastolic	14
Sodium pentobarbital	21.8	19.9
	19.5	25
Urea derivative	20.5	18.5
	13.2	17
Sodium amytal	18.2	16.5
	30.2	26
N-tolyl butyl ethyl barbital	18.0	16
	13.3	17
Neonal	17.5	15.5
	13.2	17

Comment

Four Patients with Moderate Congestive Heart Failure—These patients were much more restless than those of the first group. Sodium pentobarbital was the only hypnotic which did not increase sleep movements. All the other hypnotics consistently produced a more restless sleep. Sleep following the use of hypnotics in this group was not accompanied by a fall in

FIG 12

FIG 13

pulse rate which was greater than that following the use of a placebo. Reduction of the respiratory rate and blood pressure was present, but to a less marked degree than in the normal group. Hypnotics in this group increased the length of sleep only twenty minutes. We observed that patients with congestive heart failure became very restless when their blood pressure, pulse rate, and respiratory rate fell after the use of hypnotics. They would move about, cough, turn without waking, and in that way raise their blood pressure and pulse rate. This procedure would be repeated several times throughout the night, never allowing a fall in the blood pressure, pulse rate, and respiratory rate comparable to that of the patients without congestive heart failure.

Summary

By this method of objective clinical testing, we studied the hypnotics, sodium pentobarbital, sodium amytal, Neonal, N-tolyl-butyl-ethyl-barbital, and unsymmetrical ethyl-o-ethylphenylurea, and com-

pared their effect on sleep with that of placebos.

We made the following observations:

The time of onset of sleep was not influenced by these hypnotics.

The average length of sleep was increased about twenty minutes.

The sleep pattern, as measured by the number of gross movements made during sleep, was not changed except in patients with congestive heart failure. In these instances the hypnotics increased the number of movements made during sleep.

The pulse rate, respiratory rate, and blood pressure in subjects with normal cardiovascular mechanisms was consistently depressed by the hypnotics, while patients with congestive heart failure showed very little change.*

RUMANIA HAS 1,074 CENTENARIANS

There are 1,074 persons over 100 years of age in Rumania, according to figures published in a book by The Central Statistical Institute, the regular Bucharest, Rumania, correspondent of the *Journal of the American Medical Association* reports.

According to the book, the correspondent says, the population of the kingdom this year is 19,-

535,398. Of these, about 60 per cent, that is 15,926,178, live in villages, and the number of the urban population is only 3,609,220.

Since the last census in 1930 the birth rate has fallen from 35.2 per thousand to 31.5 per thousand. The death rate, however, did not follow the rate of decrease of births. It decreased only from 21.2 to 19.8.

PRESENTING CERTIFIED MILK TO THE PROFESSION

SAMUEL ADAMS COHEN, M D , New York City

(Member, Milk Commission of the Medical Society of the County of New York)

ALTHOUGH the state of health of an individual is dependent upon many factors, it is plainly evident that the diet or daily food intake is the determining factor. Good nutrition is the key to attaining and maintaining good health.

The history of the medical profession reflects the pioneer work and missionary spirit of its struggles and progress toward sounder and better public health through better food products. An outstanding exemplification of progress is that of the inception and development of certified milk. Since the plan of certified milk was introduced in 1893 by Dr. Henry L. Coit for "clean, safe, pure, wholesome milk, the best which the knowledge of the time could produce," the medical profession has given freely of its time and energy to carry these altruistic and constructive efforts into practical effect. Out of these efforts came the Medical Milk Commission. Today about two-thirds of the states of the country (including every important center), Hawaii, and Canada have Medical Milk Commissions, whose mission (aided by expert personnel) is to direct actively and supervise the production, milking, transportation, and distribution of certified milk.

The members of these Milk Commissions, who are appointed by, and function for, local medical societies, serve without pay. It is their careful and vigilant surveillance that gives its complete assurance that certified milk is superior to all other milk in vitamins, mineral content, and other nutritional elements, as well as in freshness, cleanliness, safety, uniformity, flavor, and protection from contamination.

Unlike many other foods, milk is readily graded by definite and practical yardsticks. Included in these criteria are a determination of the total number of bacteria and of organisms of the Bac-

terium coli group, the nutritive value of the milk (including vitamin content), taste, and butter fat content. Apart from such analysis, routine procedure calls for the checking of veterinary supervision and feeding of the dairy herd, farm inspection, examination of environmental factors that may contribute to the betterment of the milk, periodical examination, and medical supervision of all employees handling milk. Similarly the process of gradation is concerned with milking, handling, transportation, and distribution—including time limit for delivery—as well as with the sanitary conditions under which milk is bottled and the special methods and materials used in capping, sealing, and avoiding contamination. It is the strictest application of these and other criteria that establishes certified milk as superior to all other grades of milk—an assertion that is fully substantiated by an ever-increasing and imposing array of published evidence in the possession of the secretary of every Medical Milk Commission. Hence the unanimous opinion of all authorities on food and nutrition that certified milk should be recommended for those who want the best grade of milk.

So much has been written on the virtues and advantages of milk as a food for the infant, growing child, adolescent, and adult that it would be redundant to discuss here the many details of this almost perfect food. It will suffice to observe that pure milk is practically indispensable in the daily diet of the child for its optimum growth and development and that milk is a valuable aid for better nutrition for the adult. The general nutrition of any community can be fairly well estimated by its daily per capita intake of milk. For children particularly, the nearer the per capita consumption is to a quart of milk daily, the more likelihood

there is that these children will adequately fulfill their all-important requirements of protein and essential mineral salts. Thus, the total intake of milk consumed by the children of any community furnishes a fairly reliable guide to the nutrition and therefore the health of the children in that community. In the light of these facts, the desirability for presentation to the medical profession of data about certified milk is illuminated.

Certified milk was originated by a physician to raise the standards and production of milk. Since Dr. Coit's initial concept, certified milk has been and is today the one and only food product over which the medical profession exercises direct control and supervision. The high idealism embodied in securing a cleaner, safer, and more nutritious grade of milk has been overwhelmingly endorsed and ardently sponsored by the medical profession through the agency of these Medical Milk Commissions. And always, without hurry and without rest, the Medical Milk Commissions, in cooperation with health authorities, Departments of Agriculture, private laboratories, and individual organizations, and with all others interested in better milk for the consumer, have made notable progress from the very beginning of their existence because these groups were always dominated with the spirit to furnish the public with the highest quality milk obtainable. Therefore, the label "Certified" as applied to milk is in reality a far-reaching public health contribution of a Medical Milk Commission.

Ever since 1909 the methods and standards employed in the production of certified milk have been revised from year to year at the annual convention of the American Association of Medical Milk Commissions in accordance with advancing scientific knowledge.

One important result of this voluntary elevation of standards of the production and distribution of certified milk is that it automatically raises the standards of all other grades of milk. The standards of certified milk today will be the standards of other grades of milk tomorrow. In

substance, the acknowledged leadership of certified milk by all the other grades of milk is exemplified by their adoption, later, and by their willingness to accept the standard and pace set by certified milk. It seems evident, therefore, that the more widely certified milk is recommended by the profession, the keener will be the desire and interest of all progressive milk dealers to produce this highest quality of milk in order to meet the increased demand. Furthermore, this growing demand for the best grade of milk by the public will directly or indirectly act as a stimulus for "better grades of milk" to those in the milk industry, who for one reason or another are interested only in conforming to the minimum standards of their local health authorities.

While the medical profession has time and again taken a decided stand and it should now be responsible for the elimination from the market of foodstuffs detrimental to the health and welfare of the community, it has been too prone, unfortunately, to underestimate its power of leadership by not wholeheartedly endorsing the highest qualities of various foodstuffs. Hence the existence and functioning of the Medical Milk Commissions represent the leadership of the medical profession in an unusually happy role.

It has been noted repeatedly that the more conversant physicians are with the superiority of certified milk the more insistent will they become in having their patients use it. Similarly, physicians who recognize the significance of this highest grade of milk will also become increasingly receptive to evaluation of the advantages of other high quality foodstuffs for the improvement of their patients' nutrition and health.

As with other achievements of the profession its increase of public interest in the advantages of certified milk will enhance the profession's direction and influence of leadership in advocating other highest quality foodstuffs. The Medical Milk Commissions automatically obligate themselves to maintain the leadership of certified milk among all grades of milk.

PRESENTING CERTIFIED MILK TO THE PROFESSION

SAMUEL ADAMS COHEN, M D , New York City

(Member, Milk Commission of the Medical Society of the County of New York)

ALTHOUGH the state of health of an individual is dependent upon many factors, it is plainly evident that the diet or daily food intake is the determining factor. Good nutrition is the key to attaining and maintaining good health.

The history of the medical profession reflects the pioneer work and missionary spirit of its struggles and progress toward sounder and better public health through better food products. SPAS

"Have Spas an Essential Place in the National Economy and How Responsible Is Organized Medicine in Its Efforts to Promote and Control Their Activities?"

JOHN CARROLL, M D , New York City

IN APPROACHING the presentation of this paper before the State Society today I felt, as many of you no doubt do, that in bringing such a problem is like carrying coals to Newcastle. The profession has plenty of problems, some a source of justifiable resentment—problems presented by some of our legislative leaders which are cloaked in a spirit of benevolence that reeks with political expediency, and which are sure to result in injustice and confusion among the classes they propose to serve. Our problems are piling up proportionately almost like the national debt, and like that, too, they must be grappled with and solved. Fortunately there is cause for hope that the solution of the spa problem is a step in conservation rather than dissipation of national wealth.

I cannot see other than an affirmative answer to the first question raised by the title to this paper "Are Spas Essential to the National Economy?" Other nations have long thought so and have increasingly accepted responsibility for the development, protection, and guidance of these enterprises. They have realized through them a quite general use of health-promoting natural resources on the part of their people and a substantial addition annually to the national wealth, including many millions of dollars from America. The European who treasures health and vigor has made the annual cure an essential to his routine of life. The medical profession there has entered actively in the continuation and progress of these curative enterprises. One does not ask the same question about the spas of European countries. They have been and are essential, and as such are nurtured

by an appreciative awareness that includes the whole commonwealth. But the question of whether or not spas are essential to the national economy is one that must be settled as a basis of determination of wherein lies responsibility for their development and regulation. They have existed through several generations, have thrived, and some of them have established a reputation for curative results that compels acknowledgment of a therapeutic value in the agency. Lately, most of them have experienced less patronage and the quality of service has suffered. This development threatens their very existence. The depression years explain a part of the difficult position they occupy, but not all can be so ascribed. Rather in a lack of confidence and support by the medical profession rests the major cause in the conditions now existent. By way of explanation the voice of medicine says that few of the resorts are worthy of their patronage. And this comes from the profession in whom in this country the leading cause of death is degenerative heart disease, causing 40 per cent of their deaths, while among the general population heart disease is responsible for 23.85 per cent of deaths. Heart disease among physicians, including cerebral hemorrhage and arteriosclerosis, increased from a low of 33.73 per cent in 1933 to 40.52 per cent in 1935, a rate five times as great as that of pneumonia, the second ranking cause of death.

The statement that few of the health resorts are worthy of patronage by the profession may well be so, but the need of such service is detailed by Wallace in his paper in the *J.A.M.A.*, August 8, 1936, "The Modern Health Resort."

*Read at the Annual Meeting of the Medical Society of the State of New York,
Syracuse, April 26, 1939*

Therefore, every idea or advancement which carries with it a chance for improving the nutrition, quality, packaging, or distribution serves to strengthen this leadership

In their earliest days, the Medical Milk Commissions were mainly concerned with cleanliness of certified milk. Soon steps were taken by the Commissions to eliminate the danger of disease which might creep into the milk at any stage from the very source of production to its final distribution to the consumer. The Medical Milk Commissions soon discovered that eternal vigilance, fortified by the laboratory, is necessary to assure the consumer of a clean, wholesome, superior grade of milk.

More recently the nutritive quality of milk has been further enhanced, particularly in content of mineral salts and vitamins. Moreover, to secure more uniform quality, the herd producing certified milk is now to be barn fed the year round with a carefully prescribed ration, thereby overcoming the daily and sea-

sonal variation of its milk supply. The quality and quantity of rations for the dairy herd giving certified milk are under meticulous control in order to obtain a milk supply of optimum nutritive ingredients. The preparation of certified milk begins, therefore, with the soil itself.

Even such matters as taste are considered—since the most pleasing taste of milk is always an added incentive to its consumption. Recent research has so improved the taste of certified milk that today its delicate flavor is far superior to that of all other milks.

Again, experiments are now being conducted to produce a milk—certified soft-curd milk—which might be even more readily digestible by infants, children, and adults. Other examples of research in progress today, such as the formulation of methods and standards of certifying goat's milk, further testify that the devotion to the professional ideals and the pioneer spirit upon which certified milk was founded continues today undiminished.

Annual Registration Due January 1

Every practitioner of medicine and surgery in New York is required by law to apply annually on or before January 1 to the secretary of the board of medical examiners for a certificate of re-registration, on application forms furnished by him, and to pay at that time a fee of \$2. The law authorizes the secretary of the board to permit secretaries of duly incorporated medical societies to act as his representatives, to receive and transmit to him such applications and fees. Practitioners are liable to severe penalties for failing to register and for continuing in practice thereafter.

PETER IRVING, M.D.

Secretary, Medical Society of the State of New York

A goodly proportion of these people who make costly excursions to vacation land annually for restoration of vigor and health fail by a large margin to get their moneys' worth and the monetary loss entailed is often the least of the price paid. Cost values of chronic disease to the country are indicated by such studies as Emerson's reported in the *American Heart Journal*, February 1, 1929. He estimated the amount expended in the United States on the care of chronic disease as from \$89,525,000 to \$116,273,000 annually. Dublin's estimates based on 1927 records show that the cost of death from heart disease in 1928 would amount to \$21,960,000,000 in wealth to the commonwealth during the life span. These figures are staggering and in a way incomprehensible, but they do direct attention to a self-liquidating aspect of local, state, and national authority interest in spa resources. Spas in America as in Europe are the pattern upon which an organized attack upon the problem of prevention, care, and rehabilitation of the chronically ill can be effectively approached, and from which should grow the realization of Singer's wish to the medically supervised vacation migration. We need spas for the chronically disabled who have the need and urge to salvage in length of and efficiency of their years of life, and the profession of medicine which has the responsibility and care of these chronically ill and to which they look trustingly for direction, guidance, and care. There are many professional minds with experience in the field who believe that valuable data in aid of treatment of degenerative diseases will be uncovered by such studies as are possible in well-integrated spa regimen.

There is no place to compare with a modern health resort in its advantages in establishing and regulating the diet of the patient. The variety and amounts can be controlled directly through the service channels with little, if any, consciousness on the part of the patient that a dietary regimen is operating. The practice of delivery of order slips to the physician's desk keeps him constantly informed on

varying appetites, eating habits, moods. The individual waitresses become, with little training, sounding posts to the digestive systems of their charges. The relief to the patient in the apparent freedom from restraint and from the mental strain of caloric arithmetic is often noticeably helpful in creating a happier mood. The regular habits of rest and exercise with the mild gymnastics such as the Swedish movements are often sufficient to realize normal elimination. In most American spas little if any emphasis is put upon strong catharsis waters such as characterizes the Carlsbad spa.

Control of and regulation of exercise in the spa regimen is of great importance, and of paramount importance to every individual below par. The variety and amount of exercise in many conditions such as heart disease, vascular states, metabolic diseases, obesity, malnutrition, anemias require as precise definition as drugs and diet. At the modern spa there are trained technicians in passive exercise—the Zander apparatus, the graduated incline, paths, and the more strenuous forms of golf, tennis, and horseback riding. Exercise within the capacity of the heart and body to do easily is the best therapeutic agent known, but the evaluation of the kind and amount often requires an experienced physician's judgment. Rest and repose will allow a patient with embarrassed circulation to realize compensation at basal levels, but restoration of compensation in activity requires skilled management of exercise.

Our plea then is for a searching effort on the part of the medical profession for ways and means in nurturing and supporting spas so that they may function properly in an ethical and creditable way. Criteria in regulation and control when it comes should be by agreement jointly arrived at by cooperative representatives of organized spa personnel with interested and informed members of medical societies. The first need is for the medical profession to become spa minded, the doctor to realize that the development of the modern health resort is as necessary to his future as his aid and sup-

An appraisal of its possibilities is irrefutable and it would seem as if there was a proportionately greater need in our own profession. Chronic disease is rapidly increasing and we are without knowledge of means in prevention, reversal of the change, or arrest. The people realize the growing ravages of involutionary changes, and the impotence of the profession when confronted with results. They are turning to quackery and high-pressure salesmanship for the solution at a staggering cost in money. Chain stores, beauty parlors, drug vendors, proprietary medicine manufacturers are exploiting a harvest that should legitimately go to support the medical profession.

The outcome of the modern trend in medical thought has been that while medicine, established upon a firm scientific foundation, has advanced to an unbelievable degree, the art of medicine has suffered. As Persal points out, the general practitioner, finding it difficult to keep pace with the rapidly succeeding changes that have taken place in medical practice, has been gradually superseded either by out and out specialists or by a group of clinicians who by reason of their ultra-scientific training have come to look upon patients more as interesting clinical material than as individuals seeking aid for illnesses that are quite as often dependent upon maladjustments in their domestic and social environment as upon objective pathologic changes, and which require for their correction a broad-minded, sympathetic point of view on the part of a medical adviser. The public has become conscious of this fact. The intelligent layman, fully alive to the incalculable blessings that medical progress has bestowed upon him, is equally aware that as medicine has advanced it has become more impersonal and more specialized. Medicine has changed, but the psychology of the patient has not. For the most part they still manifest a desire for personal service much the same as they did in the time of our forefathers, in spite of the advances that have taken place in medicine. They want their doctor to be health adviser. They know

the secret of longevity propounded by Dr Oliver Wendell Holmes—to have a chronic disease and take care of it. They want to know the ways and means, how to avoid diabetes, kidney diseases, obesity, premature vascular accidents. Preventive medicine is on the lips of the rank and file of people.

Singer, in his paper on medically supervised vacation migrations, points out that the European, whether ill or not, seeks the advice of his physician on the choice of site, and if suffering from a chronic disease he prefers the atmosphere of the health resort with its medically supervised regimen. He contrasts the average American whose conscious motives are a change and a good time with neglect of the chance to improve his health and thereby his real sense of well-being. The great group of Americans who suffer irreparably from this neglect are the chronically ill who are aptly classified by Singer as the real forgotten people of America. Here the medical profession and the country have a large problem, a problem measurable only in billions of dollars when judged from one angle, and hundreds of thousands of discouraged broken individuals, and it ranks first in reasons for the need of the resources of the modern health resort. We know nothing exact about the prevention and arrest of chronic diseases, at least about the underlying involutionary changes, and the changes in the body economy concerned with vigor. With the control of the great epidemic diseases and other advances in preventive medicine the span of life has been steadily increased. The result is that where once the acute infections played a destructive factor, now the degenerative diseases incident to advancing years and the wear and tear of life have become the most important causes of disabling illness. The incidence of morbidity is mounting rapidly. We have no means in our armamentarium to prevent the growing ravages. They develop in the home environment. Hospitalization fails to reverse and arrest the condition and often aggravates it.

that a well-organized spa or health resort should be characterized by

- 1 The presence of natural resources, such as mineral water, peloids (mud or moors), or climate, which have therapeutic value
- 2 Suitable physical facilities for administering the above-mentioned natural therapeutic agents
- 3 Competent medical supervision
- 4 Adequate medical records and facilities for investigation.

In considering these points there is no question regarding the adequacy and variety of natural resources in this country. Mineral waters of all types are found. Peloids, both organic peats and inorganic muds, for therapeutic use are available. Thousands of miles of seashore with both temperate and semitropical climates exist for regulated ocean bathing. Climate resorts both inland at high or low altitudes and on the seashore may be developed.

Suitable physical facilities for the use of these agents differ with the type of natural resource. Some require a large physical plant. The provision of suitable living accommodations is made in some places by the institution, and in others the patients are cared for in hotels or boarding houses in the community.

Medical supervision is of two types. In some places the physician is directly attached to the institution, and in others the physicians in private practice in the community furnish the medical advice. The latter method is practiced in the larger spas. In any case, the treatments should be under the supervision of physicians.

Adequate records are necessary to establish sound clinical information regarding the results obtained from the treatment with the natural modality used. Investigation, both laboratory and clinical, is important to aid the proper evaluation of the results.

The committee also recognized the need for a central controlling council or committee which would not necessarily dictate the exact layout and operation but which would advise the management on proper procedures, assemble information for the medical profession, and promote the study of these valuable natural facilities.

The American Medical Association through its Board of Trustees has just appointed a committee of five men representing widely scattered sections of the country to take up this study and offer concrete suggestions for better utilization of these natural resources, including mineral waters, seaside treatment, peloids, and climate which are of such great value in the maintenance of the health of our people.

Spas have been criticized because the cost of treatments has been prohibitive for the individual of moderate means. In the larger spas, such as Hot Springs, Arkansas, and Saratoga Springs, New York, provision is made for all groups of people. In both places many patients receive treatments without charge after it has been established that they need the treatments and that they are not able to pay the usual fees. Also there are many smaller spas where the cost of treatment is moderate.

The author has stressed the health aspects of a spa. A regular periodic sojourn at a spa offers the finest opportunity for an annual health survey. This is certainly one important factor in the prevention of serious chronic disease, since the discovery of any condition in its early stages offers better opportunity for its control.

The natural agents when properly applied have their place in the treatment of many chronic conditions. They should not be considered as something apart from other methods of treatment. The physician may use them in conjunction with other types of therapy to provide a balanced therapeutic program for many of his patients.

Dr Charles I. Singer, *Long Beach, New York*—A survey of spas and health resorts performed by a committee of the American Congress of Physical Therapy plainly shows that the American spas are in the midst of a vicious circle. The spas, one of our national assets, show a decline in the number of patients. This is due partly to the depression but mainly to lack of medical support in recommending patients for cure. A financial deficit ensues followed up by desperate efforts of the spas to get out of red. They do it by emphasizing the entertainment values of the spa becoming centers of a good time, of recreation instead of re-creation. Secondly, they try to do it by approaching the public above the head of the medical profession with partly unfounded or antiquated claims.*

The way out of this decline is not an easy one. At its best it will be a hard uphill struggle. But two words in my mind clearly point toward success. These two words are research and education. Research performed in the spas delving into the biologic and patho-biologic effects of spa therapy which is composed of a change of environment, climate, bodily and emotional relaxation, and variegated methods of physical therapy. This research will disclose

* These unsupported claims and lack of reliable information carrying authority explain the meager interest for the spas shown by the general practitioner.

port are to the future of the enterprise. He should foster patronage by his patients, and join efforts to increase interest of the lay people. The increased cost in overhead to the spa management in meeting the requirements of the ideal pattern will make the adjustment an impossible financial burden unless sustained patronage grows with improved facilities. The doctor must recommend his patients, who will be benefited by such a regimen, to a suitable place and then lend his efforts to making the experience one of benefit and satisfaction to the patient. He must cooperate and advise with the spa physician in planning or adjusting the regimen so as to gain maximum benefit and satisfaction. The member of the profession that must be reached and made aware of the implications of this problem to his responsibility is the general practitioner and this effected by such means of publicity as County Society meetings and medical periodicals. Spa physicians should be invited and encouraged to contribute to medical meetings the report of studies and papers that set forth the advantages of the spa regimen. We should see an end to the timidity or inferiority state that has seemed a part of the spa physician. His timidity has been due no doubt to the fact that he considers himself proxy or for a few weeks the patient's family doctor. But this should not deter him. A follow-up would materially aid a study in results in therapy.

A very appropriate beginning has been realized by the action taken by the American Congress of Physical Therapy meeting at Cincinnati, September, 1937. At this meeting a committee was appointed to assemble data regarding spas and health resorts of the United States. Their report was published in the January *Archives of Physical Therapy*. It is in the field of physical therapy in its broad aspect of hydrotherapy, mechanotherapy, electrotherapy, and climatology, that the foundation of the scientific specialism of the spa physician should be grounded. With this his training should be broad, and he should be trained to appraise the total personality and treat the individual,

not the disease, and be able to teach people how to keep well. The roots of the tree of knowledge for spa physicians should reach back to the first days of the medical college course and his development mature as naturally as the otolaryngologist, dermatologist, the neurosurgeon. In addition to the above basic knowledge the spa physician should have clinical experience that fits him to appraise intelligently the type of case for which the waters are empirically indicated. If the waters are carbonated brine waters and recommended in heart and circulatory disorders the physician in care should be competent in that field. If the spa is of the sulfur variety and advanced as cures for arthritic dyscrasias, the physician should be an authority in this field. Affiliation with the national societies concerned with the study in the class of diseases to which the spa caters by publicity channels should be obligatory, and a system of certification of qualified physicians and systematized record system should be inaugurated by a committee of these societies. The societies in mind are such as the American Congress of Physical Therapy, American Heart Association, American Gastro-Enterological, American Climatological, and American Committee for the Control of Rheumatism. Scientific medicine is necessary to efficiency in the spa regimen—even more so if possible than in the most highly specialized hospital service, and if it is a natural part of the spa physician in his professional social affiliation, the spa easily functions with credit and material success.

Discussion

Dr Walter S. McClellan, *Saratoga Springs, New York*—I can heartily agree with Dr Carroll's answers to the double question incorporated in his title. Spas have an essential place in our national economy and the medical profession is responsible for their proper development and conduct.

I wish to consider as part of my discussion the "Report on Spas and Health Resorts," made at the Congress of Physical Therapy, and referred to in the paper. The committee in its report (*Arch Phys Ther* 20:42 (Jan) 1939) stated

EARLY RECOGNITION OF MENTAL DISEASES AND THEIR TREATMENT

CLARENCE O. CHENEY, M.D., White Plains, New York

(From the Department of Psychiatry, Cornell Medical College, and the Clinical Service of the New York Hospital—Westchester Division)

IT IS unnecessary to emphasize to an audience such as this the medical and sociologic importance of mental diseases. You will recall that in the recent hospital number of the *Journal of the American Medical Association*, it was shown that in 1938 there were more than 590,000 beds in nervous and mental hospitals in this country as compared with 425,000 beds in general hospitals. During 1938 nearly 200,000 patients were admitted to these nervous and mental hospitals. In New York State the 66 nervous and mental hospitals available reported approximately 100,000 beds, over 30,000 admissions, and an average census of nearly 91,000. The cost of care of these patients in New York State is over \$35,000,000 a year. It is well known to you that aside from these hospital patients there may be as many more persons in the community suffering from partially or completely incapacitating mental disorders, these disorders causing not only a loss to the individual patients but to society at large. In the time allotted to us we wish to outline briefly some of the early signs of the various groups of mental disorders and to indicate something of their treatment.

First let us consider the mental disorders of the aged. As medical science has brought about a reduction in the mortality in infancy, childhood, and middle life from communicable and infectious diseases, the span of life has been added to so that there is an increasingly large number of elderly persons surviving at any one time in the community. The longer a person lives the greater the chance for developing a mental disorder. Admissions to public hospitals of persons suffering from senile dementias are two

and a half times the proportion of elderly persons of similar age in the general population. I paraphrase the Biblical statement to, "What shall it profit a man if he add ten years to his life and lose his mind?" This situation gives pause for thought but we as physicians do not expect to cease our efforts to prolong life. In the present economic stress these elderly persons have become an increasing burden, particularly in cities. Many elderly people reach a ripe old age and die peacefully in full possession of their faculties. A large number, however, for varying periods before their death, and frequently before the age of 70, begin to show mental disturbances of senility with changes in disposition, an increasing forgetfulness, and an inability to concentrate or to grasp new conceptions. These may be recognized by the physician and the relatives of the patient as normal senescence. However, not infrequently we see apparently keen-minded elderly persons develop ideas of suspicion and persecution directed often against their own relatives and especially their children. They complain to the neighbors and to the police that they are being mistreated, poisoned, and robbed of their money. Because of their apparent keenness these stories are believed by outsiders and result in embarrassment or annoyance to the responsible relatives. The children of such patients frequently become angered at what appear to be willful attempts to bring about trouble and what may formerly have been happy families become families beset with dissension.

The physician has an opportunity here to make clear to the relatives of these old persons their irresponsibility and the

an array of new scientific facts, will give authority to claims and healthy material for educational propaganda. The American Medical Profession is not at fault in lacking enthusiasm for spas. The spas have to prove that they deserve enthusiasm as they do deserve it. American spas are superior to European health resorts in physical equipment and in the standard

of comfort they offer. If the American spa will surmount the European places in their research and educational program, and I hope it will, it will be due to such stimulating lectures as Dr Carroll's and to men with good judgment, knowledge, and educational ability like Dr McClellan, and to the Committee on Spas of the American Medical Association.

THE QUALITY OF MEDICINE

That was the subject chosen by Dr Nathan B. Van Etten, president-elect of the A. M. A., for his address at the annual banquet of the Indiana State Medical Association at Fort Wayne on October 11. The problem of choosing the quality of medical care that America is to have faces us today, and Dr Van Etten asked: "What kind of medicine do you want? Do you want England's Medicine, or Hitler's Medicine, or Stalin's Medicine, or New Zealand's Medicine, or American Medicine?"

"Do you want Socialized Medicine, or State Medicine, or Democratic Medicine? Do you want impersonal medical care or do you want free choice? Do you want bureau medicine or medicine fostered and promoted by those who have been especially dedicated to the service of the sick? Do you want the doctor an employee of the State working limited hours for a salary?"

"Shall we be dominated by dictators or by the needs of the people? The future of medicine will be determined by our citizens. If our citizens are ignorant, the practice of medicine will suffer, if they are informed, American Medicine may go forward. Medicine has survived the rise and fall of many civilizations. I predict that its advances can be only temporarily delayed and that they will attain greater heights long after the actors of the present generation have left the stage."

"You must not take a negative position. Through the influence of systematized adverse

propaganda an impression has been created that the medical profession and especially the American Medical Association is *against* all progress, *against* any change in delivering medical care, and is acting in restraint of those who would try new plans.

"People should be told that these aspersions are untrue, unfairly presented, and they should be told what American medicine really stands for."

"Organized medicine stands *for* the protection of children from all communicable diseases by scientific methods and *for* the care and improvement of deformed or crippled children. *For* the protection of children from accident and injury—*for* the protection of children from blindness. *For* the protection of children from exhaustion of child labor. *For* the care and protection of children from tuberculosis. *For* nutritional improvement. Organized medicine through private practitioners and through hospital practitioners has been steadily improving the growth and health of children for many years."

"Organized medicine stands *for* prevention of communicable venereal diseases. It stands *for* public health—*for* sanitation—*for* good education—*for* good food and drug laws—*for* good housing."

"It stands *for* better education of physicians to implement them for the practice of better medicine."

"MASSACHUSETTS COMES CLEAN"

At long last the Commonwealth of Massachusetts has taken measures for the protection of its citizens in medical affairs comparable to those of other states, remarks the *J. A. M. A.*, editorially. For years graduates of low-grade medical schools unable to obtain licenses in any other states have flocked to Massachusetts.

Two such schools not recognized in any other state have flourished almost under the shadow of the State House. In theory people were protected by the licensing examination, it is well known, however, that competence to practice medicine cannot be determined by a written examination alone. A written examination might as well be expected to test ability to paint a picture or to shoe a horse. The state has provided no machinery for a practical examination,

which is the only kind of examination worth while in ascertaining fitness for medical practice.

Now, however, by the Acts of April 30, 1936, and May 2, 1938, amending section two of chapter 112 of the General Laws, it has been decreed that no one may enter the licensing examination who is not a graduate of an "approved" medical school. There has also been created an "Approving Authority," which is to determine on request whether any medical school fulfills the requirements formulated and published by it.

The way is now clear to enforce a standard for admission to the practice of medicine at least as high as the standards prevailing generally throughout the United States. After 1941 Massachusetts should cease to be the dumping ground of unqualified practitioners.

tal symptoms described above, with neurologic signs and positive spinal fluid findings, point to a diagnosis of general paresis. As you all know, the treatment of general paresis holds out more hope than it did before the introduction of tryparsamide or fever therapy. In our experience tryparsamide is the best arsenical for the treatment of general paresis. This may be interchanged after a treatment of fourteen or fifteen weeks with a bismuth preparation. If fever therapy is available and the patient's general physical condition warrants it, this should be tried either by the method of malarial inoculation or by the hot-air cabinet. The length of these treatments depends entirely on the individual and his reaction. Fever therapy may well be followed by tryparsamide, the latter should precede malarial treatment when the patient is in a much reduced physical condition.

A mental disorder, frequently in the form of a delirium, may develop during almost any infectious or febrile disease. It appears that certain persons, especially high-strung, unstable types, are more prone to develop deliriums than the more phlegmatic types. These delirious reactions are apt to be worse at night and such patients should always be carefully watched whether in hospitals or in their own homes to prevent them from sudden attempts at suicide. One can never be sure that the delirious patient will not suddenly and impulsively make such an attempt without previous warning. Such protection should be carried out by constant nursing observation rather than by restraint, the latter is apt to provoke increased physical strain by resistance and may enhance exhaustion. Sedative drugs also, we find, are apt to increase the delirium and confusion. Not infrequently we have to treat in mental hospitals drug deliriums that have been brought about by sedative medication during physical illness. The forcing of fluids and the maintenance of an adequate diet with ample vitamins is very definitely indicated in these delirious reactions. Where the mental disorder is essentially of a delirious nature with a febrile reaction the

outlook for recovery depends upon the physical condition. If the patient improves physically the delirious reaction clears up. However, we see not infrequently that infectious disorders, such as influenza, precipitate a more constitutional disorder such as a manic-depressive reaction or dementia praecox and here the prognosis may be independent of the physical disorder, these patients continuing in just as characteristic manic-depressive or dementia praecox reactions as those we see develop without reference to infectious disorder. Varying degrees of a constitutional tendency to dementia praecox combine with varying degrees of febrile reactions to make a variety of clinical pictures that not infrequently are puzzling for prognosis. It is therefore difficult, if not impossible, to make a prognosis of a delirium during a febrile disorder without knowing something of the patient's previous personality characteristics and tendencies. These latter will determine the eventual outcome from a febrile delirium. If a patient has been on the verge of developing dementia praecox the febrile attack may be just enough to tip the balance and more or less permanently upset his adjustment. On the other hand, if a person has had a constitutional tendency to be of a manic type he is more apt to develop a frank manic reaction in association with a febrile delirium and have the usual course and outcome of such a manic reaction. The same applies for depressive persons. The clinical pictures that are not so clear and are more puzzling are seen in those patients who after a febrile disorder continue to show bizarre, sometimes impulsive, erratic behavior with apparently fixed delusions. The prognosis, however, depends much upon the clarity of the sensorium. As long as such post-febrile persons are not clear as to their whereabouts or in their thinking and are unable to concentrate, delusional ideas and erratic behavior do not necessarily by any means indicate a bad prognosis. Some of these patients clear up completely after months of confusion. If, however, patients are clear as to their sensorium

nature of their disorder and to advise tolerance, patience, and disregard of the old persons' complaints. Provision should be made for the conservation of these old persons' resources, if necessary, by the appointment of committees. It is a matter of experience that elderly people are apt to do better with strangers who understand them than they do with their children who still remain youngsters to them and from whom they are not willing to take advice or suggestions. Therefore, often the placing of such a senile paranoid person in a nursing home, or in a home for the aged where he will be associated with a group of his own age, leads to a subsidence of the paranoid ideas and comparative complacency.

Other elderly persons who have previously retained their mental faculties may become acutely delirious and confused and agitated after a minor illness such as bronchitis. These old persons have to be carried through their acute illness with caution. They react badly to sedative drugs and the administration of such drugs may increase the delirium rather than improve it. Further, in such patients the heart action may be weak and may require stimulation particularly if the blood pressure has previously been high. The high blood pressure in an old person may be much more beneficial to him than a low blood pressure, and attempts to reduce the blood pressure in elderly persons may result in a prostration and delirium and exhaustion. If supportive treatment of the heart and circulation and ample fluids and a nutritious diet do not reduce the delirium and confusion and agitation, a sedative such as paraldehyde, which is less toxic than many others, may be used to produce quiet and sleep.

If a middle-aged man who previously has been active and successful in business begins to complain of unusual fatigability and lack of concentration, shows temporary forgetfulness, and has periods of confusion, it is worth while determining what the cause of this may be and what can be done about it. It may be found that he has hypertension with or without

evidence of degenerative arteriosclerosis. The younger he is, or the more marked his hypertension and the more advanced the retinal sclerosis, the poorer the prognosis, and his family should be warned that a rapidly progressive mental enfeeblement may be expected if meanwhile a cerebral shock does not carry him off. In such patients there may not only be mental deterioration but before this occurs, paranoid ideas and suspicion and explosive outbursts of rage or irritability may show themselves. The irritability, we think, is evidence of exasperation which the patient feels as a result of his appreciation of his declining mental ability—a reaction to frustration. Tolerance and patience are essential in caring for these patients. Men of sixty to sixty-five who have developed a degenerative type of arteriosclerosis may show the same clinical mental symptoms. Here the physician can often do much in laying out a plan of living which may prolong the lives of these persons for a fair number of years. A letting-down in work or complete retirement, ample rest, freedom from causes of excitement, a sensible diet, and living in a warm climate may restore these arteriosclerotic men to a comparative mental clarity and a cheerful old age. Here again vigorous attempts at reduction in blood pressure may be detrimental to these patients who have oftentimes reached a certain stage of equilibrium with their comparatively high blood pressure. Extreme dietary restrictions also may be fraught not only with lack of success but with detriment to the patient. A complete upsetting of the bodily mechanisms is not the best treatment of these patients.

The above-mentioned hypothetical man with certain clinical symptoms may have on the other hand an early or moderately advanced general paresis. A negative blood Wassermann will not rule this out. Many syphilitics are treated nowadays to the point of having a negative blood Wassermann. This does not mean that the central nervous system has not been involved and they may go on and develop characteristic general paresis. The men-

young women admitted to psychiatric hospitals illegitimately pregnant because someone who should have been responsible for them had not sensed that they were in an abnormal irresponsible mental state requiring protection

Again, we recall the case of a young man who was looked upon as the most brilliant senior student at a university and was considered an admirable leader because of his many activities, but when he began to tell the president how to run the university and gave speeches to collect a crowd on the campus, it was realized that something needed to be done. As he sensed that something was in the air for him he for a time escaped his friends but eventually returned and came voluntarily to the hospital where he went through a characteristic manic attack with many expansive ideas, particularly with reference to his own power. It was found, also characteristically, that this exuberance was a compensation for a feeling of defeat in that he had not been able to reach a level of athletic activity that his brother previously had acquired in the university. He recovered within a short time and has since done well. He understands himself better now than he did before and there is no necessity or certainty of his having another attack.

On the other hand, not a few young persons become depressed and hopeless at what they sense as defeat. An attempt at suicide, not infrequently successful, may be the first obvious symptom of such a depression, but if one is keenly aware of the possibilities of such reactions in students as well as in older people and if one does not disregard as trivial, evidence of a slowing down and discouragement in such persons but rather gives them opportunity to discuss their difficulties, one may be saving not only lives but prolonged distressed periods of depression. It is still remarkable to us how frequently repeated thoughts and wishes for suicide and even attempts at suicide seem to be disregarded or minimized by families and at times by physicians so that patients are allowed without hindrance to carry out their wishes for death. Perhaps it

would not be so unfortunate if such persons were always those for whom little if anything in the future could be expected but, on the contrary, such depressed suicidal persons are frequently those who may be expected to contribute materially to science and other disciplines if they could be given just that temporary protection and supervision which they need while they are in their depressed phases. If we leave no other thought with you this afternoon I hope that we may have emphasized sufficiently the thought that persons who talk of suicide and particularly those who are depressed and gloomy and discouraged should not be looked upon as merely talking for effect but should be taken seriously, and protected.

It is not always, however, the most depressed and retarded patient who is the greatest suicidal risk but the patient who is coming out of a depression and is being faced with a return to his previous mode of living whatever it may have been. Such a facing of facts is often a severe threat to depressive persons and it is at such times when they seem to be recovering that they should be looked upon particularly as grave suicidal risks. It is only when the depression is completely lifted and there seems to be again some joy or happiness in living with pleasant thoughts for the future that the protection against suicide may be discontinued.

The practitioner of medicine sees dementia praecox reactions before the psychiatrist has them brought to him. They are evidenced frequently in the gradually increasing withdrawal from social and other outside contacts, often with a distorted interest in mystical or philosophical literature which probably is just as incomprehensible to the dementia praecox patient as it is to many of us, but perhaps gives him a sense of kinship because these mystical productions are as vague as some of his own thinking which he realizes is different from the thinking of the other boys and girls or young persons around him. He tries to compensate for this inability to face reality by being different from others. He tries

and appear able to concentrate and do not have dips in the levels of their consciousness, and at the same time maintain the delusional ideas, possibly with hallucinations, the prognosis is not so good, and the chances are that one is dealing with a dementia praecox reaction

It is unnecessary for me to indicate to this audience that mental disorders are not infrequently associated with pregnancy and the puerperium. We used to speak of puerperal psychoses but our recent studies indicate that the puerperium is not associated with any specific characteristic psychosis or mental disorder, but that these stressful periods for women may act as precipitating causes for manic-depressive and dementia praecox and psychoneurotic conditions. Because of the comparative infrequency or absence of puerperal sepsis at the present time, one is not apt to see frequently the delirious reaction of puerperal fever. But women patients who develop manic-depressive or dementia praecox reactions before or after childbirth have to be carefully nursed and observed, especially to see that they do not injure themselves or their children. Suicidal and infanticidal ideas are not infrequently present. Anticipation and recognition of these may save the lives of not a few mothers and children. During these abnormal reactions resentment against the husband or rejection of him completely is not infrequent, particularly if the mother did not want the baby or if she did not want her husband to be the father of her baby, or if she had had doubt of her own maternal ability. These rejections may be quite temporary and the husband should be reassured that they do not mean necessarily a permanently unhappy married life. I think all of us have seen women who in marked manic excitement have cast the most vituperative epithets at their husbands and who upon subsidence of the attack appear again to be affectionate spouses. Attacks such as these with complete loss of inhibition seem at times to act as safety valves for relief of emotional tension and when the pressure is relieved it seems easier to make a

smoother, happier adjustment to marriage

Last Christmas in a department store I was waited upon by a young woman who seemed quite intelligent but who appeared especially exuberant and "fresh" in her conversation. I wondered where the department store had gotten her and how long she would last with them. Two months later she was admitted to our hospital in a frank manic attack. I found that previously she had been through a period of a depression and then had swung into an overactive elated state, at the beginning of which she seemed to make a good impression on people and had many worth-while ideas about business. When the Christmas season was over, however, she became more overactive and insisted on marrying a young man, and when he suggested waiting for a reasonable time this young woman who had been brought up in a very respectable conventional family insisted that she wanted to live with him whether she was married or not. The family felt there was something wrong with her then and were supported in that belief when she began to hear the young man's voice from a distance and maintained that her nurse was an angel exerting a religious influence on her. Such is not an infrequent history that we obtain in young women who have conflicts in making an adjustment to their college activities and classmates or in their love life with young men, and who feel that they are not able to come up to the expectations and standards set by their families. Such young women as well as young men may develop elated excitements with much overactivity and particularly a heightened sexual interest which makes them appear vivacious and attractive but not infrequently leads to embarrassment and catastrophe if they are allowed to continue unhindered in the community. The young woman I mentioned was fortunate in having a stable sensible young man as a love object who had not taken advantage of her. Such a fortunate situation does not always exist, however, and we see too frequently

therapy that we have been accustomed to use

We have had no personal experience with the use of metrazol as we have not used it and have not advocated its use because of the violence of the convulsions it produces. The undue stresses it places on the human organism have been well shown by the dislocation and fractures of bones reported by its users, and more recently there has been demonstrated the comparative frequency with which compression fractures of the vertebrae are found so that in some hospitals, at least, its use has been discontinued.

We do not wish to attempt here an extensive analysis of the comparative results obtained in the treatment of dementia praecox by the use of insulin, metrazol, and other psychiatric procedures. However, we may call attention briefly to some statistics. Malzberg² has reported that at the termination of insulin treatment of 1,026 state hospital dementia praecox patients, 13 per cent were recovered. At the end of a year among this same group nearly half of the recovered patients had shown a relapse, but others previously considered improved and even unimproved had reached a condition to be called recovered, so that the total number recovered at the end of a year was practically the same, viz., 12.9 per cent. The catatonic types showed the highest recovery rate, 17.4 per cent.

With 1,140 state hospital dementia praecox patients treated with metrazol the recovery rate reported by Pollock⁴ was less than 1 per cent. With the same number of dementia praecox patients in the state hospitals treated with the usual methods there was a recovery rate of 3.5 per cent.

Drewry and I studied the results obtained in 500 dementia praecox patients admitted to the New York Hospital—Westchester Division and treated by the various intensive nonspecific methods available at that hospital. At the time of discharge 7 per cent were recovered.⁵ By information obtained subsequently covering periods of time elapsed from slightly less than twelve months for some

cases to over ten years for others, we found that we could report 12 per cent recovered—approximately the same as Malzberg's figures for insulin-treated cases, and that the recovery rate for the catatonic patients had doubled from 10 per cent at discharge to 20 per cent at the time of follow-up—the latter figure being somewhat greater than the recovery rate for catatonic patients reported by Malzberg after the elapse of a year following treatment with insulin.

We cite these figures not as final indications of the results of insulin treatment but to show that dementia praecox patients recover without the use of insulin. The latter, as we have already suggested, may shorten the course and decrease the period of hospitalization. How long the effects last, it is difficult to say. We see rapid relapses in some cases and holding of recovery in others. A second course of insulin treatment helps some and seems to have no effect on others. The treatment must be individualized and, it is perhaps unnecessary to say, should be carried out only in hospitals where any emergency can be met and by physicians who have had experience with the method.

We cannot discuss here adequately or comprehensively the many psychoneurotic reactions and their treatment. We may only make a few remarks which we hope may be pertinent. These persons have often shown their emotional instability and "nervousness," frequently with excessive introspection of their somatic and psychologic functions from childhood or youth. Often they have appeared to be frail reeds, easily tossed from one side to another by what are to them storms of life but which to others more robust would be gentle stimulating breezes. They react excessively to average stimuli through their circulatory, gastrointestinal, and respiratory systems. Many of them have never learned to work toward sensible goals in life. With feelings of inadequacy, probably determined by their inadequate constitutions, they overcompensate and strive eccentrically to reach aims that are beyond their

to build up his own ego and attempts to make a go of life. When the family physician sees a situation such as this we feel it is time to get at the bottom of the disharmony and try to guide these youngsters into what we call sensible thinking and activities. The unfortunate part of it is that such early dementia praecox patients are often looked upon as brilliant students, as having unusually brilliant minds, and are held up as shining examples to the more average but more healthy and balanced youngsters. By the time they are recognized as psychiatric problems they are apt to be so muddled in their thinking and so withdrawn and absorbed in weird fantasies that it is difficult to get in contact with them or to get them straightened up. It is probably because of this unfortunate delay that so many apparently hopeless cases of dementia praecox have previously been admitted to state and other hospitals.

I am not entirely willing to say that one can absolutely prevent the development of a dementia praecox reaction because it obviously is difficult to prove that one has prevented anything when it does not occur. On the other hand, the fact that one has apparently not been able to prevent the development of dementia praecox, as one sees it at a late stage, does not mean necessarily that it might not have been prevented. We see not a few youngsters and adolescents who seem to have the same conflicts and at times strange reactions that are found in those who later are clearly dementia praecox patients. But these other youngsters in some way or other, perhaps with help, work out their problems and their own salvation and go on and live well-balanced lives. We have an idea that the fundamental constitution or make-up of the individual is what determines whether or not he will develop dementia praecox under certain stresses or strains, but on the other hand we have a definite feeling that there are persons who are constitutionally disposed to develop dementia praecox who do not necessarily go on to that development. The development of a frank dementia praecox mental dis-

order may, we feel, be avoided in a predisposed person by the finding for him of a suitable niche where he lives within his capacities and is not forced or pressed beyond them by somebody else, or does not strive to get beyond his capacities because of his own inner dissatisfactions. Such a person may be a dementia praecox personality but he may, because of a combination of circumstances, be able to live out a fairly satisfactory life at what might be considered by some persons a rather low level of adjustment. Dementia praecox is not, as we see it, a disease entity. It is a type of reaction or a form of adjustment attempted by such persons who are unable to meet life as most of us have to and who because of a constitutional deficiency or inadequacy do not develop to a maturity of life. Or, if they have by some chance gotten almost to maturity they slip back quickly and easily to a less mature, often childlike, level of activity where they have little responsibility. If they are unable to find a place in the world where they can get along comfortably with the feeling of security, they develop a psychosis with muddled, panicky, distorted thinking. Persons who develop dementia praecox later in life are those who have been constitutionally more adequate and have reached a higher level of adjustment, but who nevertheless are unable to run a complete and full course of life in competition with others.

I may be expected to say something about the insulin treatment of dementia praecox. My feeling is that it is not a specific cure for dementia praecox but that it shocks certain types of cases into a physiologic or psychologic state where the patients develop either a desire to get away from their previous disordered thinking and behavior or acquire a feeling of dependence and comfort with the physician treating them so that he is able to give them the feeling of security which many of them have been longing for. This method of treatment may bring about beneficial results more quickly than other methods of treatment by occupation and socialization and psycho-

THE ROLE OF BUROW'S SOLUTION IN DERMATOLOGY

FRANK C COMBES, M D , New York City

LOUIS A DUHRING, that master of therapeutics, once said that the successful treatment of skin diseases depends upon a thorough knowledge of the pharmacologic action of the remedy employed. Several years ago I presented before this section a paper on "The Role of Sulfur in Dermatology."¹ The remedy I have chosen for today's discussion does not enjoy so wide a field of usefulness, but nevertheless is an invaluable agent in the relief of many ills of the integument. In the employment of any remedy we should be familiar with its chemotherapeutic action, have a general knowledge of its composition, and know what results to anticipate.

Karl August von Burow,² a Prussian surgeon of the nineteenth century, originally suggested the solution which, in a much modified form, we use at present. The preparation was quite astringent, much more than that prescribed in the *National Formulary* of the United States. Von Burow's particular interest lay in ophthalmologic and plastic surgery. The solution was used as a compress in the repair and regeneration of traumatized tissue and as a stimulant to epithelization of epidermal transplants. His original formula and directions for its preparation were as follows:

1	Lead acetate (crystalline)	100 grams
	Distilled water	300 grams
2	Alumen	66 grams
	Sodium sulfate	12 grams
	Distilled water	500 grams

The two solutions should be mixed cold and allowed to stand for two days at a temperature of 10 C., then filter without washing the precipitate.

Since von Burow first suggested the solution which has since borne his name it has undergone many modifications.

Even at the present day its composition varies. I have illustrated the more important changes by enumerating the formulas preferred by various writers.

Billroth	Alumen	5 grams
	Lead acetate	25 grams
	Distilled water	500 cc

Von Zumbusch	Alumen	5 grams
	Lead acetate (basic sol.)	25 grams
	Distilled water	500 cc

Hager's Handbuch der Pharmaceutischen Praxis		
Potassium alum		95 grams
Lead acetate		151 grams
Distilled water		700 cc

The solution was not used very extensively in this country until well after the turn of the century. The Third Edition of the *National Formulary* included a preparation of aluminum subacetate which at that time was in use in Germany and referred to as "Burow's Solution," although it differed materially from the original formula.

Aluminum sulfate	300 grams
Acetic acid	300 grams
Calcium carbonate	130 grams
Distilled water	1,000 cc

This actually produces a 7.5 to 8 per cent solution of basic aluminum acetate. The *National Formulary* never did refer to this preparation as Burow's solution. The first preparation referred to as "Liquor Burowi" was published in the Fourth Edition (1916) as follows:

Lead acetate	150 grams
Aluminum sulfate	85 grams
Distilled water	1,000 cc

Thus, however, being an imperfectly balanced formula, a change was made in the Sixth Edition, increasing the amount of aluminum sulfate to 87 grams. I will

capacities and become panicky and obsessed with doubts and fears at the threat of failure. Psychoanalysis in the Freudian sense is not the treatment for the larger number of these nervous persons, even if it were practicable to expose them to it. What many psychoneurotics need is education in living, with a program laid out for them of occupation and diversion that lies within their capacities, mental, physical, and financial. The start is made with a careful, painstaking study of the life history, with all the facts available regarding the early impacts of family, friends, schools, and work—an investigation of the ambitions and goals sought, their achievements and frustrations—in short a study of all the possible influences and their effects which have brought the individual as he is to us for help. It is only by so knowing an individual that one can reasonably arrive at conclusions regarding the material we have to deal with and what plan can be made for modifying that material so as to make it a better coordinated organism for fairly successful living. Recognition and acceptance of a limitation in capacity is one of the essentials. From there on it is often possible to work out a plan of activities that is within the limits. Along with this goes an encouragement of the worth-while assets, guided along sensible lines and not according to the previous eccentric muddling. Oftentimes such a treatment of the psychoneurotic may be begun best in a psychiatric hospital where

the atmosphere promotes a feeling of security and where a program of occupation and socialization may be combined with proper psychotherapy and training in living. Here, too, physical studies and treatments may be carried out as indicated for the particular patient.

We have attempted to discuss today some of the aspects of recognized mental disorders. May we leave a final thought, however, that every patient we see has mental or psychologic components which influence his reaction to sickness and may determine the outcome of the disease from which he suffers. The whole psychologic setting in which disease occurs—the patient's conception of what he suffers from, his concern about its effect on his family, his job, and his future, whether he is gaining much or losing much by his illness and whether or not he wishes to get well—all these are of importance to the patient and to the doctor in treating the patient. The sick man may not have a recognized mental illness but he may be mentally sick and he needs all the understanding and help his physician can give him.

MEDICAL-DENTAL CONFERENCE

The ninth annual medical-dental convention arranged by the joint committee of the organized medical and dental professions of the city of New York, was held on December 4 at the Hotel Pennsylvania. Presiding officers at the morning and afternoon sessions were Joseph Wrana, M.D., Pres. Queens County Medical Society, George E. Milani, M.D., Pres. Bronx County Medical Society, Clyde H. Schuyler, D.D.S., Pres. First District Dental Society, Howard Fox, M.D., Pres. Medical Society of the County

of New York, Philip I. Nash, M.D., Pres. Kings County Medical Society, and William McGill Burns, D.D.S., Pres. Second District Dental Society. On the program were papers read and discussed by Max J. Futterman, D.D.S., Albert F. R. Andresen, M.D., Clyde H. Schuyler, D.D.S., C. Raymond Wells, D.D.S., Edwin Boros, M.D., Samuel Charles Miller, D.D.S., George H. Dow, D.D.S., Sol Fineman, M.D., Walter A. Coakley, M.D., Robert Heinze, D.D.S., and Samuel Blaustein, D.D.S.

precipitated lead sulfate from the solution

4 According to the current edition of the *National Formulary* Burow's solution is prepared as follows

Lead acetate	150 grams
Aluminum sulfate	87 grams
Water qs ad	
	<hr/> 1,000 cc

Each salt is dissolved in 500 cc of water and mixed cold by pouring the lead acetate solution in a thin stream, with constant stirring, into the aluminum sulfate solution. The mixture is stirred occasionally and then the clear liquid is siphoned off. The magma is then transferred to a filter, and enough water added through the magma to make the filtered mixed liquids measure 1,000 cc. Only the clear solution is dispensed.

On the basis of molecular weights given in the equation below, calculations show that when 150 grams of lead acetate are used, the amount of aluminum sulfate necessary to precipitate all of the lead as lead sulfate is 87.84 grams instead of 87 grams specified. This is an improvement on the 85 grams of the N. F. IV and V, but is still not quite sufficient.

If you use 87 grams of aluminum sulfate, the amount of lead acetate necessary is only 148.55 grams instead of 150 grams specified.

It seems, therefore, that the lead acetate is in excess and would be present in all preparations of finished Burow's solution when made according to the *National Formulary* specification.

An excess of lead acetate, amounting to 1.45 grams (150.00—148.55) is equivalent to 0.079 gram of lead per 100 cc. of solution. This is only slightly higher than the average of solutions A, B, C, and D. I should like to raise the question here as to whether the *National Formulary* procedure should not be revised. It might even be preferable to add an excess of aluminum sulfate to insure the precipitation of all the lead.

Therapeutics

The usefulness of *Liquor Burowi* has been but slowly appreciated in the United States. Whether this has been due to ignorance of its many virtues or a result of some dissatisfaction with the *National Formulary* preparation, I do not know. Properly dispensed and intelligently used, it has definite beneficial effects upon the inflamed integument. I have enumerated the more important of these as follows:

- 1 Buffer action
- 2 Astringent and antiphlogistic actions
- 3 Antiseptic action

Buffer Action—Before considering the chemical processes involved in the buffer action of *Liquor Burowi*, a few words regarding the variations in pH readings of the cutaneous tissues may aid in appreciating its action. Schade, Marchionini, and others⁵ have shown that the pH differs in the various layers of the skin. The surface (corneous layer) varies from pH 5 to 3. Pillsbury and Schaffer found slightly higher values. The basal cell layer is but slightly less acid. The cutis vera and subcutaneous tissue approach the pH 7.35 of blood serum. Simple erythematous dermatitis without vesiculation increases the acidity of the epidermis. Erosions, lacerations, and exudative inflammations reduce the acidity of the skin surface. Readings as high as 7.44 have been determined in the eroded skin. The seepage of alkaline serum on the surface is an active factor in the spread of dermatitis due to contact substances both by continuity and contiguity. Resolution of an exudative inflammation and healing of excoriations and lacerations are accompanied by a rapid regeneration of the normal acid reaction in the epidermis. This recuperative process is definitely hastened by compresses of a buffer solution.

When an acid or a base is added to pure water there occurs a rapid dissociation and a sudden change in the hydrogen ion concentration of the solution. A buffer is a substance which will prevent or

show presently that even this amount is not quite sufficient to precipitate all of the lead acetate

The solution is a clear, colorless liquid containing in each 100 cc not less than 4.8 grams and not more than 5.8 grams of aluminum acetate ($\text{Al}(\text{C}_2\text{H}_3\text{O}_2)_3$). It has a faint acetous odor and a sweetish taste. Its specific gravity at 25 C is about 1.022 and its pH varies from 3.7 to 4.5. A sharp distinction exists between the Burow's solution of all European countries and that of the United States. What is referred to here by that name actually has no existence in the pharmacopoeias of Europe, where the solution of aluminum subacetate is in general use. It corresponds roughly to the Liquor Aluminum acetate of the Third Edition of our *National Formulary*, published in 1906.

On numerous occasions it has been observed that Burow's solution has caused irritation, even when used in dilution of 1-10. This led me to inquire whether or not there might be some variation in its preparation and composition which might be responsible for this unexpected and unfavorable reaction. Several samples were collected from various sources and examined for the presence of lead and hydrogen ion concentration, with the following results:

	Lead (Pb) Gm /100 cc	pH
A	0.24	4.05
B	0.013	4.00
C	0.002	3.95
D	Trace	3.70
E	None	4.45

The lead was determined by precipitation as the sulfate. Estimations were also made by the Chromate Method and the Dithiazone Method. All three were checked very closely, although the Dithiazone Method gave slightly higher results. In the pH determinations a glass electrode was used. It will be noted that there was no relationship between the lead content and the pH determinations. Samples A, B, C, and D were all prepared according to the *National For-*

mulary. Sample E was prepared from a commercial aluminum acetate powder, 5 grams dissolved in 100 cc of distilled water.

Notwithstanding the fact that distilled water, unless sterile and sealed, will from day to day give variations in pH readings, the difference in the various samples tested was too great to be explained on this basis. Furthermore, these differences were not great enough to account for any irritation. Pillsbury and Schaffer³ have shown that the unbroken skin will tolerate solutions of pH minus 1, and the abraded skin will react only slightly to solutions of pH 2.

It was considered possible that the free lead acetate might be the responsible factor, because of its marked astringent action, or some idiosyncrasy on the part of the patient. It has been demonstrated by Hammet⁴ that lead has an inhibiting action on the local repair and growth of skin by stopping the mytosis through the fixation of the lead by the sulfydryl radicals present in the epiderm. Since sulfur is necessary for the normal development of epidermis, this deprivation would interfere with the recuperative process following inflammation. Four sources for this contamination were considered.

1 According to the *U S Pharmacopoeia*, lead acetate used in the preparation of Liquor Aluminum acetate should contain three molecules of water of crystallization. If the salt has not been kept in tightly sealed containers it will dry, losing so much of this moisture as to upset the formula, resulting in an excess of nonprecipitated lead.

2 Commercial lead acetate contains traces of lead carbonate and sulfate. Its substitution would result in an excess of lead in the finished product.

3 For convenience in dispensing, especially in some clinics, the patient is given a mixture of lead acetate and aluminum sulfate powder. He is instructed to dissolve a teaspoonful in a pint of water for local application. The resulting solution is almost always irritating as no attempt is made to remove the pre-

peated addition of aluminum acetate would result in a concentration on the dressing which might prove irritating. No attempt should be made to cover the dressing with any impervious material such as waxed paper, oiled silk, or rubber tissue as it prevents free evaporation and may result in the retention of heat and maceration of the tissues. The entire dressing should be changed every three hours as the aluminum acetate is gradually destroyed by secretions and inflammatory exudates. Greater relief is often obtained by applying the solution at a temperature between 20 C and 30 C.

Occasionally a flocculent, jelly-like precipitate of aluminum hydrate develops in the solution. It may be clarified by the addition of a little boric acid or borax.

The use of skim milk as a diluent instead of water seems to have certain advantages. Milk itself is a colloid and has been used for centuries as an application in the relief of cutaneous inflammation. Its beneficial qualities may depend upon the phosphates, mainly calcium phosphate and the alkaline salts of potash and soda. Furthermore, milk has definite bacteriostatic properties. Inhibins and mutins have been demonstrated by Dold, Wizemann, and Kleiner,⁹ which are capable of inhibiting the growth of bacteria and yeasts. Lehmann¹⁰ has suggested the use of powdered milk with the prepared aluminum acetate powder as follows:

Powdered milk	60 grams
Powdered aluminum acetate	4 grams
Distilled water	500 cc

Aluminum acetate powder can be added to fresh milk up to 2 per cent without precipitating the casein and fats. Such solutions have a pH of 6 and are colloidal in nature.

Wet dressings or poultices are seldom used in dermatologic practice, but are applicable to surgical conditions, lymphangitis, cellulitis, and abscess. On some occasions an entire organ such as a foot or hand may be immersed for several hours in a dilute solution. This is particularly useful in impetiginous dermatitis

and extensive painful ulcerations. A 5 per cent solution is an effective application for the relief of hyperhidrosis.

The prepared aluminum acetate powder is identical with that recommended in the *Deutsches Arznei Buch* No. 6. It has the advantage of constancy of composition, absence of lead, ease of preparation, stability and superiority in therapeutic effect. Its component parts are as follows:

Aluminum sulfate	100 grams
Ac. Acetic dilut	120 grams
Potassium carbonate	46 grams
Water qs	

In conclusion I wish to thank Dr. Charles N. Frey of the Fleischmann Laboratories and Dr. Bernard B. Brodie of the Department of Pharmacology of New York University College of Medicine who have so graciously assisted in the preparation of this paper.

Discussion

Dr. Marion B. Sulzberger, *New York City*—As Dr. Combes has shown in his excellent review, our simplest medicaments are well worth studying—studying from the chemical and physical point of view, from the dispensing point of view, and from the viewpoint of action and properties. No good dermatologist should prescribe a remedy which he has not studied as thoroughly as possible, of which he is ignorant regarding the smell, color, consistency, incompatibilities, difficulties in dispensing, effects, and side-effects.

Some remedies are generally dispensed in so varied a manner that this fact makes it disadvantageous to employ them. For example,

retard this sudden change in the pH value. They are solutions which have a definite hydrogen ion concentration and which are capable of maintaining their hydrogen ion concentration in spite of the addition of appreciable quantities of acids or alkalies. The aluminum acetate of Burow's solution exists in a state of continuous dissociated ionization, and is capable of correcting variations in pH values of the skin.

This buffer action is well illustrated in the following determinations:

SOL. ALUMINUM ACETATE 1:10 (pH 4.38)

Mixture	pH of Addition	pH of Mixture
n/10 HCl	1.08	3.12
n/100 HCl	2.02	3.95
n/ Acetic acid	2.36	3.18
n/10 Na ₂ CO ₃	11.38	6.37
n/100 NaOH	12.11	4.55
n/10 NaOH	13.07	6.72

Because of this sensitive equilibrium existing between the component molecules, compresses of aluminum acetate solution not only neutralize the alkaline secretions, but as the skin is capable of absorbing acids it also replaces the acids in the epidermis, thereby maintaining the natural defensive mechanism of the integument against pyogenic infection. The degree of acidity of resorcin and boric acid solutions depends upon their concentration. The acidity of aluminum acetate in any dilution is approximately the same and is based upon the buffer substances which enable it to retain a constant acid value. This is of tremendous importance since in all inflammatory dermatoses the buffer action of the tissue is disturbed.

Antiseptic Action—Cushny⁶ considers Burow's solution as having very definite antiseptic power, "much more so than some of the more generally used antiseptics, such as boric acid." Waterhouse⁷ says "for certain surgical purposes aluminum acetate solution is one of the best antiseptics, though it is unknown to most surgeons and practitioners."

I have not pursued any investigation in reference to its bacteriostatic properties *in vitro* since I do not believe this would necessarily indicate its activity on the skin, as contact with cutaneous exudates produces ionic and chemical changes in the solution. It may be said, however, that it tends to maintain an *actual* acidity unfavorable to bacterial proliferation.

Astringent Action—It is very definitely astringent. For this reason its use on extensive denuded surfaces is sometimes productive of ill effects. However, Jadasohn⁸ has shown that paradoxically a 1 per cent solution will precipitate albumin, whereas a 5 per cent solution will not. This is an interesting phenomenon and is true of many substances which precipitate proteins. On the addition of an excess, the protein is dissolved. A mild astringent effect is of value in cutaneous inflammations accompanied by edema and exudation, both by contracting the blood capillaries and coagulating the albumin in the tissue fluids, thus controlling exudation. As a local astringent in hyperhidrosis, the powdered aluminum acetate 20 to 50 per cent mixed with kaolin makes an effective dusting powder.

Methods of Application

The method of applying Burow's solution is important, as differences in its effect occur in the same way that many other remedies vary in their effect upon the integument when used in various concentrations and vehicles.

There are three common methods of application:

1. Wet compresses
2. Wet dressings or poultices
3. Immersion

Wet compresses are indicated in acute inflammations of the skin both of an infective and noninfective nature. Advantage is taken by this method of the antiseptic, antiphlogistic, buffer, and refrigerant properties. A light gauze dressing is applied, moistened with the solution diluted with ten to twenty parts of water. As the dressing dries, distilled water may be added to moisten it. This is preferred to the solution as the re-

SYPHILIS IN PREGNANCY

GIRSCH D ASTRACHAN, M D,* New York City

(From the Departments of Dermatology and Syphilology, and of Obstetrics and Gynecology, of the Metropolitan Hospital)

THERE is one form of syphilis which is eminently preventable, namely congenital syphilis. The transmission of syphilis from mother to offspring can be prevented by timely and adequate treatment given to the mother during gestation. In order to accomplish this effectively, it is necessary to know about the interrelationship between syphilis and pregnancy, the fate of the fetus, and the methods and results of treating the syphilitic mother.

This paper presents a review of the literature on the problem of syphilis in pregnancy and also data concerning 194 cases of pregnant syphilitic women. Most of the cases studied (112) were from the Metropolitan Hospital, 82 from the University of Jena Hospital¹ (hitherto unpublished data of the author's Doctor of Medicine dissertation), and 2 cases from the author's private practice. There were 58 cases of early syphilis, 2 cerebrospinal syphilis, 2 congenital syphilis, and 114 of latent syphilis.

The Reliability of the Serologic Tests in Pregnancy—It is generally agreed that a strongly positive Wassermann reaction in pregnant women (prevalence from 2.5 per cent²⁴ to 23 per cent²⁷), verified on repetition, is diagnostic of syphilis, regardless of the absence of any history of syphilis. On the other hand, a weakly positive reaction in a patient without a history of syphilis calls for further investigation and for several repetitions of

the test before syphilis can be established or ruled out. Fordyce and Rosen¹⁵ expressed an opinion that a weakly positive reaction with a cholesterinized antigen just before delivery may occur in non-syphilitic women during pregnancy, and is therefore not diagnostic for syphilis. On the other hand, McCord²⁵ claims that pregnancy does not cause any false positive reactions but it may cause false negative reactions.

Among pregnant women in the Metropolitan dispensary on whom routine Wassermann tests were taken, there were 11 cases in which one or two weakly positive serologic reactions were followed by two to six completely negative serologic reactions, performed at weekly intervals. None of these women gave any history of syphilis, and had not received any anti-syphilitic therapy before or during pregnancy. In those cases in which the results of the deliveries could be ascertained, the babies were perfectly normal and did not show any signs of syphilis (negative cord Wassermann reaction).

The number of patients with nonspecific weakly positive serologic reactions was 5.3 per cent of all pregnant women with positive blood reactions. That figure seems to be larger than the average percentage of nonspecific positive reactions. And because of that, I believe that there is a possibility that pregnancy may be the cause of nonspecific positive serologic reactions. A weakly positive reaction in a pregnant woman, verified and repeated several times, is suggestive of syphilitic infection and calls for antisyphilitic therapy during pregnancy.

The Influence of Pregnancy on the Syphilitic Process—Kemp²³ believes that pregnancy produces an inhibiting effect

* I want to express my deep appreciation to Dr. Fred Enck, Dearborn, director of department of dermatology and syphilology; Dr. Henry Safford, director of department of gynecology and obstetrics; and Dr. Sprague Carleton, director of department of urology of the Metropolitan Hospital for their permission to study the cases in their respective departments.

I also want to thank Miss Elizabeth Collins and Miss Brigand Connolly for helping me look up records in the hospital and dispensary, and Miss Blanche Tovey for her very fine cooperation in following up cases in the work studied.

lotio alba and calamine lotion "turn out" so differently from druggist to druggist and time to time that I entirely avoid prescribing them in private practice

When I returned from my Swiss and German assistanceships, I soon found that it was impossible to obtain in America the equivalent of the European "Essigsäuretonerde." I also discovered that our "Burow's solution" was often, if not inferior in action to the Essigsäuretonerde, at least much more uncertain and irregular in its effects. I then looked into the matter and found, as Dr Combes has so admirably pointed out, that each edition of the *National Formulary*, and even each druggist and clerk had his own way of making Burow's solution. We should be greatly indebted to Dr Combes for taking the first step toward the eradication of these pharmaceutic evils.

Dr Combes has spoken of irritation from Burow's solution. In the cases of irritation I have observed, the lead was not the cause. My cases were sensitive to the aluminum salts, reacting to aluminum chloride, etc., as well. Skin sensitivity to lead must be very rare indeed, and while it probably exists, I do not recall seeing a case or the report of a case.

If, as Dr Combes suggests, one were to add excess of the aluminum sulfate in order to be sure to precipitate all the lead, one would run the risk of the ill-effects of the excess sulfate. In order to obviate some of these difficulties and in order to have a preparation which is more stable, certain present European Formulaires, for example the Swiss, have now substituted a solution of the double salt, aluminum aceticotartaricum for the older, less stable solution of aluminum aceticum.

SANITY VS HYSTERIA IN BIRTH CONTROL

Scientific study and reason should replace the hysteria and exaggeration which have accompanied the dissemination and formulation of knowledge of birth control, George W Kosmak, M D, New York, contends in the *Journal of the American Medical Association* for Oct 21.

"Full consideration of the historic, social, economic, legal and medical aspects," he believes, "is necessary to a proper understanding of this complex situation."

"Undoubtedly the medical profession has been hesitant to take an active part in a propaganda with which many of its members are out of sympathy, largely because of the hysteria and exaggeration which have accompanied its dissemination. However, the profession cannot refuse to recognize the firm conviction on the part of the public that procreation can, and perhaps should, be regulated."

"As physicians, we should constitute an active and influential force by which this effort can be guided in the proper direction. There is a sane as well as what may be termed an insane ap-

proach to a question which is agitating a great many people."

In defining the responsibility of the medical profession in birth control Dr Kosmak states:

"Doctors have been looked on as obstructionists to progress in this matter. But we are not obstructionists, we are merely doubters. There has been much sentimental appeal and much loose thinking on this subject and, notwithstanding all that has been said, we are still far from a satisfactory solution of the question of whether conception can be completely or satisfactorily controlled by artificial means."

"In the meantime the physician must play his part and assume his responsibilities. Whether he concludes to limit his participation to the strictly medical indications for contraceptive advice or whether he is ready to acknowledge the desirability of spacing children or limiting their number when this is needed, he should inform himself of the necessary procedures and their proper application and look on this knowledge as a part of his treatment armamentarium."

SYPHILIS IN THE NEW BORN

"Clinical Digest of Syphilis in the New Born" is the title of the newest pamphlet released for the medical profession by the Bureau of Social Hygiene of the New York City Department of Health. The leaflet is issued in cooperation

with the United States Public Health Service and the New York State Health Department. Copies may be obtained from the Bureau of Social Hygiene, 125 Worth Street, New York City.

TABLE 1—THE INFLUENCE OF THE STAGE AND DURATION OF THE MOTHER'S INFECTION ON THE FATE OF THE OFFSPRING
(In this table the amount and type of treatment are not taken into consideration)

	Number of Patients	Number of Cases with Early Syphilis	Number of Cases with Late Latent Syphilis	Number of Stillbirths and Children Who Died Soon After Birth
Jena Hospital group	82	56	26	33 (40.2%)
Metrop. Hospital group	95	2	88	16 (16.8%)

each successive pregnancy becomes better as time goes on and the syphilitic infection becomes older

Table 1 illustrates clearly the great number (40.2 per cent) of stillbirths and children who died soon after birth, in the group which was composed mostly of cases of early syphilis.¹ The other group which was composed chiefly of cases of late latent syphilis presented a much smaller percentage of loss of life among the offspring (16.8 per cent)

Mechanism of the Infection of the Fetus—Concerning the methods of transmission of syphilis to the child, several opinions are entertained, among which are the paternal and maternal theories. The first one is generally considered to be untenable. The maternal theory is the accepted one, implying that the syphilitic infection is transmitted from the mother to the fetus through the placenta

Time of Transmission of the Syphilitic Infection to the Fetus—The fetus is in all probability infected in the latter half of pregnancy, according to Ingraham.¹⁹ Some investigators base their opinion on the fact that syphilitic miscarriages rarely occur before the sixteenth week of pregnancy, but patients known to have syphilis show a much greater incidence of late miscarriages than the nonsyphilitic ones. Among 82 cases (Jena Group) studied by me,¹ none of the miscarriages occurred in the first four months. About 75 per cent of the miscarriages and stillbirths occurred in the six-seven-eight-months period. According to these figures, we may say that syphilis very seldom causes early abortions, but it plays a very important role in the etiology of pre-

mature terminations in late pregnancy. This conception coincides fully with the opinion of Doederlein.¹²

Treatment of Syphilitic Women During Pregnancy

The main purpose in treating the syphilitic pregnant woman is (1) preventing transmission of the syphilitic infection to the offspring, and (2) the cure of syphilis of the fetus, if the latter is already infected. Because of the importance of these aims, and also because these can be attained only with proper planning and care, the treatment of syphilitic women during pregnancy must be well planned, vigorous, and continuous. If the treatment of the mother is begun early enough, infection of the fetus may be prevented. On the other hand, if the treatment has been delayed and is not started until the second half of pregnancy, such treatment will have to be vigorous enough to be able to combat the spirochetemia in the fetus.

The Value of Antisyphilitic Therapy in Preventing the Transmission of the Infection to the Offspring—Statistics and reports of different authors prove that if pregnant women are treated adequately and if treatment is started early enough, their progeny will be normal, nonsyphilitic infants in almost all cases. One hundred per cent of the mothers treated before pregnancy and maintained under treatment without intermission during pregnancy, up to the time of delivery, gave birth to normal nonsyphilitic children.²⁰ Table 2 illustrates the influence of antisyphilitic treatment of pregnant women on the fate of the children in our cases. The largest percentage of syphilitic children were born to women who were never treated (90.7 per cent). The smallest percentage of syphilitic children were born to women who were treated before and during pregnancy (31.5 per cent). The treatment during pregnancy is of paramount importance, but even a little and inadequate treatment before pregnancy helps definitely in diminishing the percentage of congenitally syphilitic children.^{9,26} The value of the therapy

upon the course of the syphilitic infection, but at the same time he thinks that there are other factors which are responsible for the changed course of the disease in the female

The lesions of primary or secondary syphilis may be greatly modified or entirely suppressed in cases where the impregnation of the ovum and infection with syphilis approximately coincide^{35 27}

The beneficial effect of pregnancy on syphilis lasts not only during the early stage of the disease, but may even last for a long time thereafter. Some authorities go as far as to suggest that pregnancy may be considered a very important factor in the building of the woman's defense mechanism in syphilis. In other words, pregnancy is considered as a valuable therapeutic measure^{34, 27}

Because syphilitic manifestations in women are very mild in character, many women are not aware of the infection. In 82 of the patients of the Metropolitan Hospital (86.1 per cent) the syphilitic infection was discovered only by a routine serologic test. These cases suffered from so-called unsuspected syphilis.³

Morbidity of the Mother During Pregnancy and Puerperium—The morbidity rate in syphilitic pregnant women differs generally very little from that of normal women, but occasionally marked disturbances in the course of pregnancy, delivery, and puerperium may occur. The healing process of the primary and secondary lesions may be markedly prolonged. Because of the fibrosis of the affected tissues, tears of the cervix or perineum may occur. Frequent perineal lacerations have been reported.^{12 17} Abnormal presentations, particularly breech, were encountered with greater frequency due probably to the larger number of premature deliveries.³¹ The course of pregnancy and puerperium in our cases was normal, with the following exceptions

Among the patients of the Jena Group,¹ there was a case of hydramnion,³⁴ two cervix tears, two perineal third-degree lacerations, and several minor and vulvar lacerations. In 17 cases a rise of tempera-

ture above 38 C was observed during puerperium. One case, presenting a severe salvarsan dermatitis with crusting, fissuring ulcerations, developed a puerperal infection and sepsis, and died after eight days. Among the cases delivered in Metropolitan Hospital, there were 3 which presented a temperature of 100 F to 101 F for six to twelve days during puerperium, 1 case of hydramnion and a few minor perineal lacerations were observed.

The Fate of the Offspring

Syphilis is a devastating disease as far as the products of gestation are concerned. About 25,000 fetal deaths from prenatal syphilis occur in the United States.³⁶

Cooperative Clinical Group studies of women with latent syphilis have shown that in 78.4 per cent of the cases, the pregnancy ended in a miscarriage or stillbirth, or in the birth of children who died in early infancy, or the birth of congenitally syphilitic children.²⁷ A syphilitic woman, untreated, bears a healthy child only in one case out of six. The ultimate fate of children born alive is also influenced by the syphilitic infection of the mothers. These children suffer from lowered resistance and malnutrition. They are more susceptible to colds, pneumonias, and other intercurrent diseases,⁹ and the mortality and morbidity rates among them are much higher than among children born of nonsyphilitic mothers.⁹ Out of 99 women (treated and untreated) delivered in the Metropolitan Hospital, 48 (48.4 per cent) gave birth to syphilitic children, 16 (16.1 per cent) were born dead or died soon after birth.

The Influence of Duration of the Syphilitic Infection on the Fate of the Offspring—According to the Cooperative Group,⁹ the stage of the mother's infection is of paramount importance with respect to the prognosis of the pregnancy. The effect of the duration of syphilis of the mother on the outcome of pregnancy is discussed also by Paley.³⁹ The older the infection, the more pronounced is the general weakening of the "virus" even in untreated cases. The prognosis of

TABLE 4 —THE COMPARATIVE VALUE OF NEOARSPHENAMINE AND MAPHARSEN DURING PREGNANCY IN PREVENTING THE TRANSMISSION OF THE SYPHILITIC INFECTION TO THE OFFSPRING

		Patients Treated with Neoarsphenamine	Number of Congenitally Syphilitic Children	Patients Treated with Mapharsen	Number of Congenitally Syphilitic Children
Total number of patients treated	35	22	14 (63.6%)	13	5 (38.4%)
Patients who received less than 5 injections	13	9	7 (77.7%)	4	4 (100%)
Patients who received less than 10 injections	25	18	12 (68.0%)	7	5 (71%)
Patients who received 10 or more injections	10	4	2 (50%)	6	0

syphilitic children born of women who received the same respective number of neoarsphenamine injections. On the other hand, the percentage of congenitally syphilitic babies of all women treated with mapharsen (38.4 per cent) is much smaller than the percentage of congenitally syphilitic babies of all women treated with neoarsphenamine (63.6 per cent).

Women who received ten and more injections of mapharsen gave birth to perfectly normal nonsyphilitic children, while the ones who received the same number of neoarsphenamine injections gave birth to two syphilitic children (out of four). These data, in regard to preventing the transmission of the syphilitic infection to the offspring, show that mapharsen is at least as good and potent a drug as neoarsphenamine. In cases of anemic, undernourished, and weak women, mapharsen, because of its lower toxicity, is preferable to neoarsphenamine.

The Use of Heavy Metals—The results of treatment of pregnant syphilitic women, as far as the fate of the offspring is concerned, are much better when heavy metal is given in addition to the arsenicals²⁴ than when the same amount of arsenical is given alone.²⁶

Because the woman is burdened with a double load as far as her excretory organs (liver and kidneys) are concerned, she should not be subjected to the full strain of very intensive treatment, and therefore it is advisable not to use the concurrent method of administration of arsenicals and heavy metal. These drugs are to be given in alternate courses. If the treatment is started as late as the seventh month, however, these two drugs should be given concurrently, once a week each, until delivery.

Which Pregnant Women Should Receive Antisyphilitic Therapy—Any preg-

nant woman with a positive serology verified on repetition, or with a history of syphilitic infection in the past, should be treated during pregnancy. It makes no difference whether the infection is of long or short duration, whether the woman was treated previously or not at all. Even if the woman in question has received the proper treatment and was pronounced cured years ago, she should nevertheless be given antisyphilitic therapy during pregnancy. Treatment during a preceding pregnancy is an insufficient protection for the present pregnancy, even if the syphilitic woman has a negative serologic reaction.⁹ The syphilitic mother should be treated throughout each pregnancy to insure adequate protection of the offspring. Where the question of Wassermann-negative and physically normal wives of syphilitic husbands is concerned, there is no need to treat them during pregnancy, unless there is some evidence of syphilitic infection in the woman's history. We do contend, however, that these cases should be observed very carefully and serologic examination performed several times during pregnancy.

The Time to Begin Treatment of Pregnant Women—The best results are obtained when the treatment is begun before pregnancy and continued without intermission up to the time of delivery (see Table 2). If the diagnosis of syphilis is established only after the woman has conceived, the best possible results are achieved when antisyphilitic therapy is begun in the first half of pregnancy and continued until term. Most investigators agree that if proper and adequate treatment is started before the fifth month, the birth of a normal, nonsyphilitic child is assured in 91 to 95 per cent of the cases.^{9, 26, 20, 28} Unfortunately,

TABLE 2—THE VALUE OF ANTISYPHILITIC THERAPY (ESPECIALLY DURING PREGNANCY) IN PREVENTING THE TRANSMISSION OF THE INFECTION TO THE OFFSPRING

	Number	Number of Congenitally Syphilitic Children
Patients who received no treatment at all	11	10 (90.9%)
Patients who received treatment before pregnancy only	5	4 (80%)
Patients who received treatment during pregnancy only	32	13 (40.6%)
Patients who received treatment before and during pregnancy	19	6 (31.5%)

TABLE 3—THE IMPORTANCE OF ARSENOTHERAPY DURING PREGNANCY IN PREVENTING THE TRANSMISSION OF THE SYPHILITIC INFECTION TO THE OFFSPRING

	Number	Number of Congenitally Syphilitic Children
Patients who received less than 5 injections	13	11 (84.6%)
Patients who received less than 10 injections	25	17 (68%)
Patients who received 10 or more injections	10	2 (20%)

depends largely on the number of injections of arsenicals given McKelvey and Turner report that when as much as 4 Gm of arsphenamine (twelve to fourteen injections) have been given, no syphilitic offspring have been observed Other investigators maintain that good results may be achieved with at least ten, preferably fifteen, injections of arsenicals^{9 24 36}

The importance of arsenotherapy is illustrated in Table 3 Patients who received less than five injections of an arsenical during pregnancy gave birth to syphilitic children in 84.6 per cent Patients who received ten or more injections of an arsenical gave birth to syphilitic children in only 20 per cent

Choice of Arsenicals and Discussion on Mapharsen

Some investigators prefer old arsphenamine for the treatment of pregnant syphilitic women, others believe that good results may also be obtained with neoarsphenamine Moore compared the results obtained with arsphenamine with the neoarsphenamine data of Roberts and came to the conclusion that either product given in proper dosage will probably produce equally good results

In a recent article, Ingraham cites 42 cases of fatal arsenical reactions (35 cases collected from the literature) and stresses the advisability of cautious administration of arsenical therapy

Because of the relatively lower toxicity of mapharsen, and its established reputation as a good antisymphilitic remedy, I used it in 24 cases of pregnancy and compared its therapeutic value with that of neoarsphenamine

Although the number of patients treated

and the total number of injections given is too small to formulate definite conclusions, the data obtained may be of interest and worth mentioning Among 24 patients who were treated with mapharsen there were only 6 who developed some kind of a reaction With the exception of a case of pruritus (two to three days' duration) and one of slight vaginal bleeding, which stopped after one hour and was not followed by any further complications (the use of mapharsen was discontinued in this case), all reactions were very mild in character Two patients complained of nausea and vomiting following the injections of mapharsen, 2 others complained of mild nose bleeding which lasted one-half to one hour The reactions in 5 cases occurred only once and did not recur after the dosage of mapharsen was diminished Because of the very small number and mild character of the reactions observed, my findings differ from those of other investigators, Cole and Palmer⁸ reported that in 5 of 11 pregnant women treated by them, mapharsen was poorly tolerated, Castallo, *et al.*,⁷ state that mapharsen causes distressing gastrointestinal symptoms, with a relative or actual loss in weight They⁷ also believe that the protective influence of mapharsen in permitting the gestation to continue appears to be definitely inferior to neoarsphenamine The therapeutic value of mapharsen in comparison with neoarsphenamine, in preventing transmission of the syphilitic infection to the offspring in our cases, is illustrated in Table 4

The percentage of syphilitic children born of women who received less than five and less than ten mapharsen injections is larger than the percentage of

In a recent article, Ingraham cites 42 cases of fatal arsenical reactions (35 cases collected from the literature) and stresses the advisability of cautious administration of arsenical therapy

Because of the relatively lower toxicity of mapharsen, and its established reputation as a good antisypylitic remedy, I used it in 24 cases of pregnancy and compared its therapeutic value with that of neoarsphenamine

Although the number of patients treated

and the total number of injections given is too small to formulate definite conclusions, the data obtained may be of interest and worth mentioning Among 24 patients who were treated with mapharsen there were only 6 who developed some kind of a reaction With the exception of a case of pruritus (two to three days' duration) and one of slight vaginal bleeding, which stopped after one hour and was not followed by any further complications (the use of mapharsen was discontinued in this case), all reactions were very mild in character Two patients complained of nausea and vomiting following the injections of mapharsen, 2 others complained of mild nose bleeding which lasted one-half to one hour The reactions in 5 cases occurred only once and did not recur after the dosage of mapharsen was diminished Because of the very small number and mild character of the reactions observed, my findings differ from those of other investigators, Cole and Palmer⁸ reported that in 5 of 11 pregnant women treated by them, mapharsen was poorly tolerated, Castallo, *et al*,⁷ state that mapharsen causes distressing gastrointestinal symptoms, with a relative or actual loss in weight They⁷ also believe that the protective influence of mapharsen in permitting the gestation to continue appears to be definitely inferior to neoarsphenamine The therapeutic value of mapharsen in comparison with neoarsphenamine, in preventing transmission of the syphilitic infection to the offspring in our cases, is illustrated in Table 4

The percentage of syphilitic children born of women who received less than five and less than ten mapharsen injections is larger than the percentage of

crepancy (18 per cent) between the cord Wassermann reports and the ultimate status of the infants, and because generally a single Wassermann test cannot be accepted as a proof of infantile syphilis, most investigators^{26 27} agree that a positive cord Wassermann test is only suggestive of syphilis and that further serologic study of the infant is indicated in order to establish the diagnosis of syphilis. On the other hand, a negative cord Wassermann test does not exclude prenatal syphilis.²⁶ It should be supported by further serologic studies. The ultimate fate of 10 of our cases, on which a cord Wassermann test was taken, was followed up. Serologic tests of the blood with or without roentgen examination of the long bones were taken within one to five months after the delivery. The children with a positive cord Wassermann test were proved to be definitely syphilitic while the ones with a negative serology of the cord were found to be free of syphilis. In other words, in our very limited number of cases, the ultimate fate of the children, without exception, corresponded fully with the results of the cord Wassermann test.

(f) *The Blood Serology of the Newborn*—The serology in the first few weeks in early congenital syphilis cannot be relied upon for the diagnosis of syphilis.^{14 15} Some infants may be born with a negative serology, which becomes positive after two or three weeks¹⁵, others may show at birth a weakly positive serologic reaction which becomes negative after one to two weeks (toxemia from the mother).¹¹ After the first three or four weeks almost 100 per cent of syphilitic infants give a positive reaction of the blood, because of this the most favorable time for the serologic examination of the infant's blood is three or four weeks after birth. It should be repeated after several months.¹⁵

Pediatric Follow-up—Some investigators³⁰ believe that if by the age of four months the infant has not developed clinical or serologic evidence of syphilis, infection has probably not taken place and the patient may be regarded as non-

TABLE 6—SCHEME FOR TREATMENT OF PREGNANT SYPHILITIC WOMEN

(It is assumed that the infection was discovered in the beginning of the third month)

Week	Arsenical	Bismuth	Method of Administration
1-2		Bism. salicyl 0 1-0 2	Once a week
3-10	Neocaraph 0 3-0 45 or maph 30- 40 mg		Once a week
11-18		Bism. salicyl 0 1-0 2	Once a week
19-27	Neocaraph 0 3-0 45 or maph 30- 40 mg		Once a week

syphilitic. However, I feel that further observation of the infant is necessary, and I agree with Turner,²⁶ McKelvey,²⁶ Moore,²⁷ and Cole²⁸ that it is safer to examine the child clinically and serologically every six months until it has reached the age of two years. Among the cases in the Metropolitan Hospital I observed 1 which proved to me the necessity of following up observation of the infant for more than four months. One of the patients gave birth to a baby whose cord Wassermann test was four plus. The blood of the infant was examined serologically two months later and was found to be negative. The test was repeated at the age of four and three-fourths months and was found to be strongly positive.

Children of Syphilitic Mothers Should Not be Treated Before a Definite Diagnosis of Congenital Syphilis Is Established—Some investigators^{38 39} believe that every child of a syphilitic mother, especially if the syphilis is in an early stage,³⁹ should be treated, even if it does not present any clinical or serologic evidence of the disease. I do not agree with this standpoint and believe that it is unfair to put the stamp of syphilis on an infant and have it undergo the long, strenuous, and sometimes dangerous treatment without definite proof of the presence of the disease. The fact that the mother is suffering from syphilis, in any stage, does not necessarily signify that her offspring is also infected. Quite the contrary, we know of syphilitic families in which some of the children were infected by the mother while others escaped. It is also known

the treatment of pregnant women is often unnecessarily delayed. Several weeks often elapse from the time of the finding of a positive blood test in the prenatal clinic and the patient's appearance in the syphilis clinic. Every pregnant syphilitic woman, however, should be treated, no matter how late in pregnancy the treatment begins. Even a few treatments during the last weeks, constituting a late inadequate therapy, may materially alter the outcome of pregnancy^{9, 26} (see Table 2), that the earlier in pregnancy the treatment is begun, the lesser is the number of syphilitic offspring⁶ is also illustrated in Table 5. In our series, the percentage of congenitally syphilitic children born to women who began treatment before the fifth month was about one-half that of women who began treatment after the fifth month.

The Routine Treatment—Table 6 illustrates the routine treatment of pregnant syphilitic women that is used in the syphilis clinic of the Metropolitan Hospital (service of Dr. Frederick Dearborn). It consists of alternate courses of bismuth and an arsenical (nearsphenamine or mapharsen). It is endeavored to give at least ten bismuth injections and about fifteen injections of arsenicals. In order to avoid Herxheimer's reaction, or violent gastrointestinal disturbances, which may interfere with the normal process of pregnancy, the heavy metal and arsenicals are started with smaller doses. The treatment is planned so that it should end with at least a few arsenicals just before delivery. If treatment is started in the seventh month, the concurrent method of administration of bismuth and arsenical is used.

Various Diagnostic Measures for the Detection of the Syphilitic Infection of the Offspring

(a) Ingraham²¹ performed *darkfield examinations* on fresh preparations of scrapings from the wall of the umbilical vein of infants born of syphilitic mothers and found that method a very useful one for the immediate recognition of the syphilitic infection of the infant. This

Pregnant women who began treatment after the 5th month	26	16 (61.5%)

method is also recommended by Moore.²⁸

(b) A *syphilitic placenta* (thick stroma, small blood vessels, packed with round cells and a marked endarteritis) suggests syphilis of the infant, but not as a final diagnosis, because cases have been reported with a normal placenta and with ultimate syphilitic disease in the infant.²⁶ A positive serologic reaction of the cord together with syphilitic changes in the placenta proved in 100 per cent the diagnosis of syphilis in the infant.²⁸

(c) Fraser¹⁶ believes that *enlargement of the liver and spleen*, fibrotic chronic inflammatory changes in these organs and also in the lungs and pancreas together with chondroepiphysitis of the long bones are the most important pathologic changes in congenital syphilis.

(d) *Roentgenogram of the Long Bones as a Diagnostic Sign*—The characteristic epiphysitis presents thickening and irregularity of the epiphyseal line, which may be replaced later by a zone of fatty degeneration and necrosis between the epiphysis.^{16, 34} According to most investigators, the presence of syphilitic epiphysitis, proved by roentgen examination, is almost pathognomonic for the existence of prenatal syphilis, and treatment should be instituted at once.

(e) *The Cord Wassermann Test*—Most investigators believe that the cord Wassermann test is of great value^{24, 26} because it points to the possibility of syphilitic infection of the infant. McKelvey and Turner²⁶ investigated the ultimate fate of infants with a positive Wassermann reaction of the cord and showed that 81 per cent of these were proved to be definitely syphilitic, while 18 per cent were later found to be free of syphilis. Because of the definite dis-

Discussion

Dr John R. Schermerhorn, *Schenectady, New York*—We believe that the first step in the treatment of any case of syphilis is that the patient should have a very thorough physical examination. Without this, we cannot choose the proper drug nor the dose to use. We also should have the duration of the disease. After these facts are established, we should select the drug to fit the disease. In pregnancy, the majority of patients fall in the young healthy individual group, that is, from 20 to 30 years of age, and these may stand a very vigorous treatment. It is a conceded fact that the drug of choice for the treatment of a young healthy individual is salvarsan, and in our experience over the last two years this fact has been borne out. We believe that salvarsan should also be used in the treatment of the healthy vigorous young pregnant women. Formerly when we used the old gravity method of administering salvarsan, several reactions were noted. In the last two years we have been using a 30-cc. syringe, dissolving the salvarsan in 35 cc. of water with a neutralizing agent coming in a separate bottle for each dose, and giving the injection slowly through a 23-gauge needle. With this method, we have had one slight nitritoid reaction. Two patients who had marked secondary lesions were given a full dose (0.45) of salvarsan and these injections were followed by an elevation of temperature to 104 F and severe chills. These reactions were the only ones that we have had in the last two years through the administering of salvarsan. We now get better results from salvarsan because the dangers of a poorly mixed solution are eliminated by having the neutralizing agent scientifically prepared in individual ampoules for each dose. By this method, a physician may use salvarsan with the same ease that he would use neosalvarsan or mapharsen with not much more trouble in preparing it and with a little more expenditure of time in administering it.

If the patient does not tolerate salvarsan, we then use neosalvarsan or mapharsen, and we agree with the findings of Cole, Palmer, and Costello, and many others, that mapharsen is not tolerated as well as nearsphenamine.

We agree with your conclusions that the earlier treatment is begun, the greater the chances of healthy normal offsprings. In regard to your statement that several weeks elapse from the finding of a positive blood test in the prenatal clinic and the patient's appearance in the syphilitic clinic—this is not a fact in the county of Schenectady. All positive Wassermanns in the county are reported to us coincidently with the

reports sent to the physicians, and our nurses will always follow up these cases either for the private physician or clinic within a few days. The pregnant women are given special attention and not allowed to relapse even one week. This service is extended to both the private physicians and also to our own cases in the clinic. I do not believe that without adequate follow-up facilities the clinic patient can successfully be treated. It is also a great aid to the private physician to be able to take advantage of the follow-up service, and to know that his patients will be returned to him without delay.

To keep these patients under treatment is a distinct advantage to all. By reporting these patients by number instead of by name, secrecy is maintained both as to the mother and the child. This method of reporting is advantageous in that the physician can use this as a lever in compelling the patient to receive continuous treatment without having her name reported for delinquency.

In the State of New York, two laws have been passed during the last year, one making it mandatory that all pregnant women have a Wassermann test done and the other compelling all people contemplating marriage to be examined for syphilis. The passing of these laws will make a great difference in the future treatment of pregnant women because the majority of cases that we will then have will be of comparatively recent infection and will need a very vigorous course of treatment.

Dr Girsch D. Astrachan, *New York City*—(in answer to Dr Schermerhorn)—The reason for the large number of stillbirths and children who died soon after birth in the Jena group of patients, in comparison with the lesser number of deaths among the offspring of the Metropolitan group, lies in the fact that the first group was composed mainly of early syphilitic cases, while the second group presented mostly cases of late latent syphilis. I did not mention the necessity of a complete physical examination of every pregnant woman, because this necessity is self-evident. I admit, however, that a reminder of this need is useful in some cases. I do not see any need for the use of old arsphenamine in cases of pregnancy. The main purpose of treating the pregnant women is not to cure the syphilis of the mother, but to prevent the transmission of the infection from the mother to her offspring. This purpose can be achieved by the use of less toxic drugs than old arsphenamine, namely, nearsphenamine or mapharsen. A pregnant woman, because of the double load on her excretory organs should not be subjected

that one of twins may be born with syphilis, while the other is born normal and remains well throughout life³⁷ Because of this, I believe that it is much wiser to postpone treatment for weeks or even months, until a definite diagnosis is established, one way or the other

The modern methods of investigation, including cord serologic test, histologic examination of the placenta, darkfield examination of the wall of the umbilical vein, roentgenograms of the long bones, clinical and serologic follow-up, will in the overwhelming majority of cases prove definitely, or disprove entirely, the diagnosis of syphilis

Conclusions

1 Many women suffer from unsuspected syphilis

2 Routine serologic test should be obligatory in every case of pregnancy

3 The morbidity of the mother during pregnancy may be somewhat increased due to the syphilitic infection

4 An untreated syphilitic woman will have a miscarriage, or a stillbirth, or give birth to a congenital syphilitic child in the largest majority of cases

5 The prognosis of each pregnancy improves as time goes on and the infection of the mother becomes older

6 Congenital syphilis may be completely prevented by adequate and early antisyphilitic treatment of the pregnant woman

7 Every pregnant syphilitic woman should be treated, no matter how old her infection is, and no matter how much treatment she received prior to her pregnancy

8 The best results are achieved when the antisyphilitic treatment is begun before the fifth month and about fifteen injections of arsenicals are given during pregnancy

9 Neoarsphenamine or mapharsen can be used with equal benefits in the treatment of syphilitic pregnant women

10 In cases of anemic, weak, or undernourished women, mapharsen is preferable to neoarsphenamine because it is less toxic

11 The cord serologic test is reliable in most cases, but it should be confirmed by a serologic test of the blood taken three or four weeks after birth, and roentgenograms of the long bones

12 Children of syphilitic mothers should not be treated before the diagnosis of congenital syphilis is definitely established

ARSENICAL HEPATITIS

JAMES RALPH SCOTT, M D , New York City

A WHITE man, aged 49, an office worker, slightly overweight, was awakened during the night with a "dull, heavy pain" in the right upper quadrant. The pain did not radiate. It was accompanied by nausea but no vomiting, and after an hour or two settled in the epigastrium. It was relieved slightly by soda bicarbonate in hot water. For the two or three days preceding the attack the patient had felt tired, and the day before the attack had lost his desire for food but had forced himself to eat his usual dinner in the evening.

When seen the morning following the attack, the pulse, temperature, and blood pressure were normal and the physical examination was negative. The following day he complained of a headache. His temperature was then 100.4 F and his pulse 92. Physical examination again was negative. The leukocytes were 10,000, polymorphonuclears 70 per cent, lymphocytes 23 per cent, eosinophiles 2 per cent, and monocytes 5 per cent. The urine was negative except for an excess of indican. Epsom salts and a fluid diet were prescribed, and the following day the patient was well.

One month later a similar attack of pain occurred, followed in three days by anorexia, headache, and a temperature of 101.6 F. The skin and sclera became jaundiced, and the urine bile colored. Stools were somewhat lighter than normal, but not clay colored. There was no diarrhea at any time. Because of the jaundice the urine was tested for arsenic at St. Luke's Hospital. Arsenic was found in large quantities—3 plus. The physical examination, except for the jaundice, was again negative.

The patient was placed on a low fat, high carbohydrate diet, colon irrigations, and forced fluids. The temperature subsided on the second day and the patient was about his work at the end of the

week. The jaundice gradually faded and had disappeared in ten days.

To aid in the elimination of the arsenic, sodium thiosulfate was given intravenously and by mouth. Sulfactol (Metz), containing 1.0 Gm, was given intravenously in 10 cc of distilled water every two days for ten days, then twice weekly for two weeks. During this period, and subsequently for ten weeks, Sulfactol tablets (Metz), 0.5 Gm, was given by mouth three times daily before meals. At the end of seven weeks the urine was tested for arsenic and found to be 1 plus. The test was repeated six weeks later and no arsenic was found. The time elapsed between the discovery of the arsenic and its complete elimination was three months.

Inquiry as to the source of the arsenic resulted in the conclusion that it was ingested with the food, particularly with the fruits and vegetables. A routine Wassermann was negative. The patient had never received any antiluetic treatment, and none of the "tonic" preparations containing arsenic had been administered either hypodermically or by mouth as far back as he could remember. The patient was particularly fond of and ate generous quantities of leafy vegetables, such as lettuce and broccoli, and during the previous six weeks while in the country had consumed two or three apples daily, in addition to his other food.

While the actual food from which the patient's supplies were obtained was not tested, repeated tests both before and since had revealed the presence of arsenic on the fruits and vegetables bought in this vicinity. The source of this arsenic is, of course, the arsenical preparations with which these fruits and vegetables are sprayed. In recent tests performed by the Department of Health of New York City, broccoli and kale were

to the full strain of vigorous antisyphilitic treatment. The latter may aggravate an existing (in some cases) toxemia. The very limited number of cases treated with mapharsen is not sufficient to allow me to formulate any definite con-

clusions. However, I believe that mapharsen in regard to preventing transmission of the syphilitic infection from the mother to the offspring, is as good an antisyphilitic drug as neoarsphenamine.

LABORATORY AIDS IN THE DIAGNOSIS OF HEMOLYTIC STREPTOCOCCAL INFECTIONS

Hemolytic streptococci are the etiologic incitants of many different infectious processes—scarlet fever, erysipelas, pneumonia, sinusitis, osteomyelitis, septic sore throat, sporadic throat infections. Laboratory examinations may aid the physician by demonstrating the presence of these microorganisms. The majority of hemolytic streptococci from human infections belong to serologic group A. Although these strains can be classified into subgroups according to other biologic characters, an etiologic relationship between the subgroups and the various symptom complexes has not been established. Thus, differential diagnosis must depend upon clinical manifestations.

Bacteriologic studies of cultures from the nose and throat are of limited practical value in the detection of carriers or as a basis for release from quarantine. Hemolytic streptococci are found in specimens from a large percentage of convalescents and also from a small percentage of apparently normal individuals. They may be found intermittently in the noses and throats of carriers who present no other evidences of infection, or they may persist after convalescence in persons to whom no cases of infection are traceable.

Epidemiologic investigations have indicated that in the majority of explosive outbreaks of scarlet fever and septic sore throat a causal relationship can be demonstrated between the cases and raw milk or other food into which the incitants had been introduced by a handler with an active streptococcal infection. In epidemics due to raw milk, hemolytic streptococci from such a handler have usually infected the udder of one or more of the cows (mastitis). The isolation of streptococci of serologic Group A from

the suspected animal, from the food handler, and from representative patients serves to complete the epidemiologic evidence. Prevention of such outbreaks depends upon adequate pasteurization of milk from healthy cows and methods of handling milk and other foods that preclude contamination.

Laboratory Aids in Diagnosis

I Nose and Throat Cultures—When epidemic or streptococcus (septic) sore throat is suspected, the Sanitary Code requires that a culture from the throat on Loeffler's blood-serum medium and the swab used be submitted for examination to a laboratory approved for the purpose. In investigations of any explosive outbreaks of streptococcal infection, similar specimens should be submitted from the noses and throats of all persons having contact with the suspected cattle or food and from representative patients.

II Exudates—Bacteriologic examinations of exudates, as from infected wounds, skin lesions, or the ear, aid in determining the incitant.

III Blood and Spinal Fluid—Streptococcal septicemia and meningitis may seem to be primary infections, but more frequently they are extensions of a localized process, as in the case of mastoiditis. About 10 cc. of blood or 5 cc. of spinal fluid should be submitted for cultural examination.

IV Milk—In investigations of outbreaks, samples from the individual quarters of each cow that has mastitis or lesions on the udder or teats should be examined for Group-A streptococci. These samples, collected under conditions that preclude contamination, may be preserved for shipment by combining 2 parts of milk and 1 part of glycerol, T P.

The New York State Association of Public Health Laboratories

Cancer of the breast has become far more common since it became fashionable for women not to nurse their babies, according to Dr. Frank E. Adair, executive officer of the new Memorial Hospital for the Treatment of Cancer, New York City, as quoted in a newspaper interview.

Early discovery of infection is a game of wits. The tubercle is relentless but without wit. The human race has wit but is indolent. Add to our wit a touch of the relentlessness of our enemy and he has no chance of survival.—Emerson, K, *Jour-Lancel*

ANTERIOR POLIOMYELITIS

Relation to Hypertension in Young Adults

HARRY DAN VICKERS, M D , Little Falls, New York

RECENTLY in the course of private practice, there came to my attention, in quick succession, a series of three cases in which arterial hypertension of moderate degree was associated with the stigmata of anterior poliomyelitis. The patients were all young adults, and in each instance other pathologic findings of significance were absent.

Case Reports

Case 1—Mr A. B., aged 28, stated that he had been refused a life insurance policy because of high blood pressure. He had had anterior poliomyelitis at the age of 14, but no permanent paralysis resulted. He had had influenza at the age of 25. He suffered from occasional colds and was subject to attacks of hay fever. His only complaint was slight pounding of the heart on exertion. He was of asthenic physique and definitely nervous constitution. Physical examination revealed some prolongation of the first sound at the apex of the heart. The blood pressure was 180/120. Routine urinalysis was negative and a Mosenthal kidney function test gave normal results. The red cell count, white cell count, and hemoglobin were within normal limits. A six-foot roentgenogram of the chest showed nothing of note. The basal metabolic rate was minus 2½ per cent. The electrocardiographic tracings were not remarkable. The blood Wassermann was negative. Subsequent blood pressure determinations have been 172/114, 154/114, 170/114, and 180/120. These readings have been spaced about six months apart.

Case 2—Mr L. C., aged 25, also stated that he had been refused a life insurance policy because of high blood pressure. He recalled no illnesses other than an attack of anterior poliomyelitis which occurred at the age of three years and which had left him with atrophy of the muscles of the left leg and weakness of the muscles of the left lumbar region of the back. There were no other physical findings of note. His blood pressure was 176/106. Routine urinalysis was negative and a Mosenthal kidney function test gave normal results. The red cell count, white cell count, and hemoglobin were

within normal limits. Blood Wassermann was negative. The basal metabolic rate was plus 10 per cent on one occasion and plus 7 per cent on another occasion. The electrocardiogram was not remarkable. Subsequent blood pressure determinations have been 176/110, 205/100, and 190/120.

Case 3—Mr G. E., aged 31, came in my office to discuss the illness of his brother, and, before leaving, casually inquired about the possible causes of a pressure sensation in his chest. His blood pressure was found to be 160/85. Inquiry revealed that he had had anterior poliomyelitis at the age of 8 years and had suffered a temporary paralysis of both legs. He had had measles at 3 years of age and mumps at 12. A few carious teeth and chronically diseased tonsils were the only pathologic physical findings. Routine urinalysis was not remarkable. The blood Wassermann was negative. The electrocardiogram was normal in appearance. Subsequent blood pressure readings were 140/85 and 150/78.

Since these three cases were seen in a very short interval of time, I was impressed by the fact that all had had infantile paralysis. A cursory search of the literature failed to reveal any mention of such an association. Blood pressure readings were obtained on a few acquaintances who were known to have had polio in their childhood and all were elevated. With the backing of this additional evidence it was decided to obtain blood pressure readings on as many cases as possible. To this end the New York State Department of Health furnished a list of poliomyelitis victims in this vicinity. This list covered cases back to 1916. These people were seen, a brief history obtained, and their blood pressures recorded. An aneroid sphygmomanometer was used. Most of them were revisited to obtain check readings, on a mercurial sphygmomanometer. I was impressed by the fact that most showed no outward sign of ever having

found to be particular offenders. The involvement of these vegetables and fruits is not a plea for eliminating them from our diet. To most persons the small amount of arsenic contained in these vegetables is not injurious. But,

as in the case here reported, persons sensitive to arsenic must be careful in their use of these fruits and vegetables. Fruits should be peeled before being eaten, and vegetables washed thoroughly before being cooked.

TRAVELING MEDICAL FACULTIES USED FOR GRADUATE EDUCATION

Traveling faculties in graduate medical education are being used by several state medical associations to insure the continued competence of the practicing physician and maintain the high quality of medical care for the people, an editorial in the *Journal of the American Medical Association* for Nov 4 points out.

"The problem of continuation study for practicing physicians is no longer one concerned exclusively with education, transportation is beginning to be of considerable importance," the editorial says. "A graduate program may be quite sound educationally and yet fail if it does not bring competent instructors to physicians desirous of continuing their studies. This is especially true in the more sparsely settled areas of the United States and in those states without medical schools.

"For the past five years the physicians of Idaho have appreciated the need for continuation study. To meet this need they have brought to the five-day annual meeting of their state association a flying medical faculty. Each year five or six instructors from one medical school have been invited to organize an integrated, correlated course of study of general interest to practicing physicians. Instruction in basic sciences has initiated discussions of clinical studies, and round table discussions have permitted attending physicians to participate.

"In 1939 the state medical associations of

Washington and Oregon arranged their annual meetings to utilize the same traveling faculty as was engaged in Idaho. Thus the physicians of three states have had the opportunity to attend, at their own annual meetings, a continuation course of study.

"Four other western states, Colorado, Utah, New Mexico, and Wyoming, have pooled their interests in graduate studies to bring, every two years to one of their states, twenty out-of-state speakers to discuss problems of medicine and public health which are peculiar to the Rocky Mountain region. The medical society in each state has been represented on the executive committee and a different state society has acted as host every two years. The first Rocky Mountain Conference was held in Denver in 1937, the second in Salt Lake City in 1939, and the next meeting is scheduled for Wyoming.

"Thus seven states, five without a four-year medical school within the borders of the state, have provided graduate opportunities for practicing physicians. Frequently physicians travel from 100 to 250 miles to attend one- or two-day regional meetings.

"There still remain, however, physicians who are unable to leave their practice even for a short time to travel the distance required. For them provision is now being made, the instructors traveling throughout the state so that continuation study may be brought to a greater number of communities."

COMING—TWO HUNDRED MILLION COLDS!

Because victims of colds do not worry about passing their affliction on to others, there will be two hundred million colds in the United States this winter, Robert Toubib, Washington, D C, estimates in the November issue of *Hygiene, The Health Magazine*.

As for treatment, the author advises "Stay in bed, comfort yourself without the use of drugs, don't blow your nose too hard, and if your throat is sore, gargle with some hot salt or soda solution.

"Because the doctors have not found a dramatic cure or prevention for colds, all the neighbors, the pseudoscientific dreamers and the commercial sharpers believe themselves licensed to attempt to solve this problem. They know that a cold infection is frequently admitted via the nose and mouth, that there are some two dozen

organisms living in the average mouth and throat, and, most important of all, the commercial sharper knows that the cold victim is the ideal sucker. On this basis, he devises a mouth wash and gargle which will kill bacteria in the least possible number of seconds.

"Sprays and nose drops shrink the inflamed mucous membrane of the nose and pharynx. Unfortunately, they also decrease the action of the ciliated epithelium those little hairlike projections which nature has provided to sweep out the secretions. Many physicians feel that the latter effect slows up recovery. However, it is recognized that under some conditions (the failure of the sinuses to drain, for example), these remedies have real value when used as they should be. The nasal douche is passing into the oblivion it has long deserved."

Case Reports

GAS GANGRENE OF THE TRUNK WITH RECOVERY AND RESIDUAL CARDIAC DAMAGE

ROBERT L. SEWELL, M D, Rochester, New York

(From the Department of Surgery, University of Rochester, School of Medicine and Dentistry)

THE presentation of this case of C Welchii infection of the trunk is prompted, primarily, because of the remarkable extent it attained, and incidentally, because of the interesting cardiac involvement occurring during the course of the disease

Case Report

F T, a 50-year-old Italian male, was first seen at the Strong Memorial Hospital on August 16, 1938, when he appeared with a complaint of "bad piles" of one week's duration

For ten years he had had hemorrhoids which occasionally caused pain on defecation, but neither prolapsed nor bled. A week before admission he first noted a painful swelling just to the right of the rectum which gradually increased in size and painfulness in the next several days. He visited a clinic in Rochester where he was given a prescription for suppositories. On inserting one, several days later, he noticed pus coming from about his rectum. Three days before admission his scrotum began to swell, became red and quite painful, and, in the following two days the persistence and the increasing severity of the pain and swelling prompted him to come here.

The family history and past history were not relevant. In view of subsequent findings it was of interest that there were no complaints or symptoms suggestive of cardiac disease.

Physical Examination—His temperature was 38.6 C, pulse 100, respiration 24. The patient was a fairly well-nourished and developed Italian male, tending to favor his perineum on changing position.

The perineal tissues were markedly swollen on the right with a central area about 6 by 2 cm which was dark gray in color and oozing a very foul, thin, dark pus. From this area a ridge of swollen red tissue extended anteriorly to the scrotum which was swollen to about four times normal size and was red and tender. Over the dark gray area could be felt distinct crepitus. On rectal examination a tender, indurated area was felt on the right about 3 cm in diameter. Prostate was normal, sphincter tone good. Several small hemorrhoids were present.

In the general examination nothing of note was found. There was increased A-P diameter of the chest, but the lungs were clear and resonant throughout. The heart was not enlarged to percussion, the sounds were of good quality, the rhythm regular, and there were no murmurs. B.P. 125/80. The abdomen was not remarkable. Urine examination revealed a trace of albumin, 4 plus sugar, and the presence of acetone.

A tentative diagnosis was made of diabetes and of gas gangrene of the perineal region, probably secondary to an ischio-rectal abscess. He was given 20 units of insulin and 10,000 units each of Vibron Septique and C Welchii antitoxin, and was taken directly to the operating room.

Under nitrous oxide and ether, the urethra was first investigated and found normal, and the perineum and perirectal tissues then widely incised and drained. Dakins tubes were inserted. A retention catheter was put in place and the patient was returned to the division. The presence of a gas infection at the time was obvious and cultures taken at operation revealed C Welchii, Escherichia Coli and a nonhemolytic streptococcus.

In the ward he appeared quite ill, but was rational. He was given intravenous glucose and parenteral fluids, and his diabetes was regulated with insulin fairly satisfactorily within 24 hours. A definite diagnosis had been made on the basis of blood sugar readings of 240 mgm per cent. Insulin requirements were about 40 units daily.

First Postoperative Day—The patient appeared much sicker and weaker, and complained of pain in the perineum and left flank. Crepitus was found extending all through the left buttock and back into the flank. He received 400 cc of blood, 10,000 units each of Vibron Septique and C Welchii antiserum and was started on sulfanilamide, 2.5 grams a day.

Second Postoperative Day—Patient was desperately ill, almost comatose, temperature fluctuating from 38.0 to 39.0 C. Parenteral fluids were maintained throughout and intravenous glucose with insulin was given. He received more C Welchii antiserum (10,000 units), by this time the crepitus was readily palpable over the left lower quadrant anteriorly, incision and drainage was then carried out over the anterior superior spine on the left and the symphysis. He was given another blood transfusion. He was also given 6.5 grams of sulfanilamide by mouth. Later in the day crepitus was found through the entire shaft of the penis as well as through all of the previously involved tissues which had become dark and swollen. He had a severe chill and was, unquestionably, critically ill.

Third Postoperative Day—He had another chill, was thereafter practically moribund, and little hope was held for his recovery. Late in the day it was decided to give him some irradiation, so he received 300 r over the anterior abdomen on the left and posteriorly over the pelvis. It was thought that the serum was doing no obvious good, so for the time it was withheld. Sulfanilamide was discontinued.

TABLE—BLOOD PRESSURE IN CASES OF POLIOMYELITIS

Case	Sex	Age	Polio at (Age)	Blood Pressure	
D A	M	17	18 mo	128/80	128/80
A B	M	17	6 mo	140/84

* Died of pulmonary tuberculosis two weeks later

had the disease, there being little if any residual atrophy in the muscle groups originally affected. There were some, however, who were badly crippled by their loss of muscular power. The majority were visibly nervous and high strung. Quite a few had rather frequent attacks of epistaxis. Curiously enough, only one of the girls examined had an abnormal pressure.

Summary

A small series of cases is reported in which arterial hypertension is associated with the stigmata of healed anterior poliomyelitis in young adults. No mention of this is found in medical literature, and it is believed that the possible association warrants further study.

TOO MUCH OF A GOOD THING

The daily soap and water bath, which has become such an important part of the American health regimen, may be an actual menace to the health of one's skin during the winter months, if taken indiscriminately, Eugene F. Traub, M.D., New York, declares in *Hygeia, The Health Magazine* for December.

He points out that lack of exposure to the sun and too much dry heat during the winter have a tendency to dry out the skin. In persons whose skin is naturally rather dry, this dryness may progress to an eczema or winter dermatitis.

Such persons, therefore, especially if they are

over 40, would do well to limit their bathing to two or three baths a week, as the alkali and other factors in most soaps act as further irritants. Bran, cornstarch, or baking soda may be added to the water to soften it. Warm water tends to extract more of the natural oil of the skin than does cool or cold water.

Suitable lubricating preparations may be applied to counteract the tendency to dryness. Goose grease, lanolin, petroleum jelly, or cold cream are all suitable, and to them may be added medicaments to promote healing, allay itching, or produce a cooling effect on the skin.

CONTUSION OF THE HEART*

JULIUS BURSTEIN, M D, and RICHARD H MARSHAK, M D, New York City

(From the Department of Electrocardiography at Morrisania City Hospital)

CONTUSION of the heart as a definite clinical entity, with electrocardiographic changes simulating that of myocardial infarction, has been known for a few years and there have been many reports in the literature describing its syndrome. The usual type of injury to the heart is of the penetrating variety. Recently, a new type of injury to the heart has been described by Beck¹ as the nonpenetrating type of injury to the heart. We have had the occasion to see two such cases at Morrisania City Hospital and, recently, a third has come under our observation.

We have been able to demonstrate electrocardiographic changes not only in the conventional three leads but also in the precordial lead. It is the purpose of this paper to stress this new type of injury causing contusion of the heart and to show the value of the electrocardiogram, with special emphasis on the precordial lead in establishing a diagnosis. It is not the object of this paper to go into a detailed description of the clinical picture of contusion of the heart, but the sequence of events in one of the two cases to be described will adequately present the syndrome.

Case Reports

Case 1—Patient is a white male, aged 37 who was admitted November 17, 1938, and discharged December 25, 1938.

History—The patient lost control of his car while driving and ran into an object, the nature of which is unknown. The steering wheel was jammed into patient's left chest. There was no history of unconsciousness. On admission, he complained of severe chest pain which was aggravated by respiration.

Physical Examination—The patient was a well-developed, well-nourished individual, in mild shock, with moderate cyanosis and dyspnea. The pulse was regular, rapid, of fairly good quality, and averaged 110 beats per minute. There was a bloody discharge from both nostrils and there were multiple lacerations about the bridge of the nose. The eyes reacted to light and accommodation normally. There was a distinct compression deformity about the lower aspect of the precordium with abrasions of skin over that area. The lungs were clear. The apical impulse of the heart was in the fifth intercostal space to the left of the midclavicular line. The heart sounds were of fair quality with a systolic murmur at the apex. The heart rate averaged 110 beats per minute and there was regular sinus rhythm.

On admission at 11 15 A. M. the blood pressure was 60 mm./40 mm. and the temperature was

98 F. No reading of the venous pressure was made, but two attempts to provide patient with an infusion resulted in clotting of the tube for a distance of six inches indicating a positive venous pressure. At 5 30 P. M. a manometer reading was 9½ cm of water pressure. At 10 30 P. M. it was 11 cm of water pressure. Blood pressure readings ranged from 60/40, 100/60, 110/66, 120/60, 120/60, taken at hourly intervals. Fluoroscopic examination revealed a quiet heart with no limitation of cardiac impulse. There was a slight enlargement of the left auricle. X-ray revealed evidence of fracture of the left fourth, fifth, and sixth ribs along the midaxillary line. The day following admission there was a suggestion of a friction rub over the apex which was transient. Fluoroscopic examination at this time showed no evidence of cardiac or pleural effusions. On November 19, 1938, the heart sounds were of good quality with a friction rub definitely heard over the apex. Venous pressure at this time was 10 cm of water. The patient was seen by a neurologist who found no evidence of focal injury, but his impression was that of a mild cranioencephal trauma. The diagnosis was made of contusion of the heart and the patient was treated with bed rest for six weeks. The temperature ranged from 100 F. to 102 F. for the first five days of admission after which it came down to normal. On November 22, 1938, five days after admission, a loud systolic murmur was heard at the apex with a suggestion of a presystolic murmur. The patient probably had rheumatic involvement of the heart despite the lack of a previous history. The urine was negative. Wassermann tests were also negative. Because of the possibility of a rupture of the heart or bleeding external to the heart, this patient was watched constantly for a possible indication for operation. However, his subsequent course was one of steady improvement.

An electrocardiogram taken November 17, 1938 (Fig 1A), showed a depressed T 1 and an inverted and diphasic T 4. On November 21 (Fig 1B), four days later, there was an inverted and coved T 2 and 3 and a diphasic T 4. On November 22 (Fig 1C), there was inversion and coving of T 2, 3, and 4. On December 5 (Fig 1D), T 2 was revealed in its normal upright position, T 3 was still slightly inverted, but T 4 was markedly inverted and coved. The tracing taken on December 27 (Fig 1E), revealed a complete return to normal as did the one taken on March 29, 1939 (Fig 1F). In the last record there is no evidence of previous cardiac damage.

Notched P 1, 2, and 3 were found to be persistent throughout the entire series of electrocardiograms in this case, and is consistent with the clinical diagnosis of previous rheumatic heart disease (mitral stenosis). This series of electrocardiograms showed definite evidence of injury to the heart, with findings simulating posterior wall infarction in leads 2 and 3. The earliest and most persistent abnormal finding was an inverted T 4 (Figs 1A through D). Specific

* Report of two cases admitted to the Traumatic Service of Dr. Emmett A. Dooley at Morrisania City Hospital.

Fourth Postoperative Day—For the first time the patient appeared to be no worse. Crepitus still present in perineum, left flank, left gluteal region, left lower quadrant, and all through the scrotum and shaft of the penis. He was given 300 r more over the same anterior and posterior portals.

The next day he looked decidedly better, was rational, and complained bitterly of pain in the penis. The crepitus remained only in the perineum and the left buttock. He was given 200 r over the same two portals in the morning and again in the evening, at which time he received 10,000 units more C. Welchii antiserum.

Irradiation and serotherapy were then stopped and thereafter he was given 5.2 Gm sulfanilamide and 10 cc of 2½ per cent Protosil daily. Sulfanilamide level in the blood was 5 mgm per cent. Irrigations were carried out with hydrogen peroxide, and the wounds began to clear up. On the twelfth day, numerous basilar rales were heard and the heart was found enlarged to the left. An electrocardiogram showed myocardial damage. The patient was rapidly digitalized and there was no further evidence of left-sided failure.

By the seventeenth day all drains had been removed and wounds were irrigated with Dakins solution instead of peroxide. The spleen, which had first been found enlarged on his fourth day, was much smaller but still was palpable. A successful secondary closure of his wounds was done and he was discharged on his seventy-third day to a convalescent home with one granulating perineal sinus.

His heart, definitely larger than on admission, had not perceptibly decreased in size during the last month and there was a blowing systolic murmur over the P. M. I. The spleen was no longer palpable but the liver on discharge descended two finger breadths below the rib margin.

The patient was last examined on January 4, 1939, over four months after admission. His heart was still enlarged as much as when he was discharged from the hospital, and the liver was still palpable two finger breadths below the costal margin on inspiration. There were no other abnormalities noted except that he had developed a ptosis of the right eyelid, associated with no other symptoms.

Examination of the extra-ocular muscles revealed apparently total paralysis of the superior, inferior, and internal rectus muscles and of the inferior oblique. No explanation is offered for this paralysis of the oculomotor nerve, for it is scarcely conceivable that it can be related to the foregoing disease.

The recent introduction of irradiation in these infections has led Kelly¹ and others to criticize the use of amputation and radical surgery in gas gangrene of the extremities, but as yet the surgeon has but little precedent to fall back on when the question of incision, drainage, or débridement occurs, for with both serum and x-ray at his disposal the problem is far different than it was ten years ago.

Certainly this man rapidly became profoundly ill following the wide incision and drainage, with rapid extension of his infection whereas he had presumably had the infection several days before he came to the hospital in only moderate

distress and had the infection fairly well localized. Even with irradiation it is evident that incision and drainage and débridement must at times be used as was necessary here. Whether the incisions prompted spread is questionable, but there was no doubt at the time the skin was laid open over the anterior superior spine and over the symphysis that the process seemed chiefly in the subcutaneous tissue and did not involve the muscle, and that the infection seemed to be extending in this region subcutaneously, while in the perineum and the buttocks all tissues were involved.

The remaining interesting feature of this case is the development of myocardial damage with early failure during the course of the infection. The experimental work of Pasternack and Bengtson² in study of the effect of Vibron Septique toxin on animals indicated almost an affinity of the toxin for the heart muscle with very obvious and predictable pathologic lesions. The signs of early heart failure in this case were not recognized until the twelfth day, which is hardly comparable with the short times found experimentally. Then, too, this man's previous cardiac status is unknown except that there had been no referable symptoms. Nevertheless, the sequence of events suggest myocardial damage following the infection.

The systemic effects of gas gangrene infections are often not noted because the customary course of the disease is so fulminant that obvious signs of damage to the heart or other viscera are not manifest. The shock of the original injury or of an amputation and the more infrequent serum reactions further distort the picture and as a result the treatment is chiefly that of a local infection.

While irradiation and perhaps sulfanilamide are valuable aids to be used in conjunction with serum, at least the former is going to have its greatest value in those infections which are somehow refractory to serum treatment. In these instances the toxin already formed and distributed systemically will neither be neutralized by an effective antiserum nor be affected appreciably by the irradiation to the local lesion. Thus such patients who survive, as this patient did, will show much more clearly than those recovering after effective serum therapy the effect of the toxin on the various organs.

Summary

A case of severe gas gangrene infection is presented in which irradiation was apparently the prime factor in instituting recovery. The occurrence of myocardial failure following the infection brings up the question of possible damage to the heart by the C. Welchii toxin.

B

C

FIG 2

T 1, 2, and 3 There was a lesser degree of inversion of T 4 than in the previous record. The progression of changes in the above series of electrocardiograms indicate definite damage to the heart muscle. The rapid graphic improvement (ten days), seen specifically in lead 4, probably indicates damage of traumatic origin. We were unable to complete this series of electrocardiograms because of lack of cooperation on the part of the patient.

Comment

These 2 cases stress the value of electrocardiograms in establishing a diagnosis of contusion of the heart and indicate its value in chest injuries. In Case 1 the clinical findings of the contusion of the heart were substantiated by the graphic findings. In Case 2 the electrocardiogram alone was diagnostic. We feel that contusion of the heart of the nonpenetrating variety will become a much more frequent diagnosis if routine electrocardiograms are taken on every case of external injury to the chest. It is our practice at

Morrisania City Hospital to take tracings on every patient with a history of injury to the chest wall in order to aid in the diagnosis of possible cardiac trauma. We recommend a careful history in every automobile accident case because of the possibility of heart damage due to chest-wall injury (steering wheel accidents, etc.)

The precordial lead was of definite value and was the earliest and most constant finding on the electrocardiogram in these 2 cases.

Summary

1 The electrocardiogram is of aid in establishing a diagnosis of contusion of the heart of the nonpenetrating variety, particularly when a clear clinical picture is absent.

2 Every case of injury to the chest should be considered in the light of a possible contusion of the heart until proved otherwise.

FIG 1

treatment consisted of bed rest and sedation. Electrocardiograms taken two months after discharge showed no abnormality (Fig 1F). Questioning of the patient three months after the accident revealed that he complained of occasional precordial distress upon exertion but had no objective findings.

Case 2—A white male, aged 32, was admitted November 22, 1938, and discharged December 7, 1938.

History—On the day of admission, the patient's car collided with another car and he immediately experienced excruciating pain over the sternum. On admission to the hospital, he was drowsy, had an alcoholic odor to the breath, but he gave no history of vomiting. During the period of observation he was unable to remember the accident. He did not complain of headache or dizziness. He did, however, complain of severe pain over the sternum at the level of the fourth and fifth ribs, which was worse on respiration.

Physical Examination—The patient entered the hospital in a semiconscious state but soon regained complete consciousness. He responded to all questions and was fairly well oriented. The blood pressure at the time of admission was 120 mm/70 mm. The examination was negative except for severe pain over the sternum with contusion of the same area. The diagnosis

at that time was craniocerebral trauma, contusion of the sternum, possible contusion of the heart, and possible fracture of the fourth, fifth, and sixth left ribs. The chest pain continued for five days. Radiographic examination of the chest revealed displacement of the xiphoid of the sternum but there was no evidence of fractured ribs. Electrocardiograms showed definite changes confirming the diagnosis of contusion of the heart. The temperature was normal except for the first three days when it was elevated to 100 F. The treatment consisted of absolute bed rest and sedation.

In contradistinction to the first case, this patient revealed no cardiac syndrome which would physically indicate heart trauma. Nevertheless, the contusion of the chest wall definitely required further investigation by means of serial electrocardiograms. A tracing taken the day after admission (Fig 2A) showed a depressed T 2, an inverted T 3, and an inverted and coved T 4. This is undoubtedly indicative of definite damage to the heart muscle. A second electrocardiogram taken five days later (Fig 2B) showed a depressed T 1 and 2. The T wave in lead 3 changed from inversion to the isoelectric level. Inversion and coving of the T wave in lead 4 was seen to be less marked. The final tracing on this patient, taken December 5, 1938 (Fig 2C), disclosed a persistent depression of

Blood pressure was 154/78. The abdomen was distended, fluid was absent, the liver was enlarged, no abnormal masses were felt. Urine 1014, trace of albumin, few pus clumps. Spinal fluid was normal. X-rays of hands, chest, and skull showed osteoarthritis of interphalangeal joints, marked dorsal scoliosis, thickened left pleura, hyperostosis of inner table of frontal bone and a calcified mass in the dura of the occipital region. Histology of a cervical node showed Hodgkin's disease.

The course was steadily downward. She developed swellings beneath the angles of both jaws, and signs of pneumonia. Death occurred June 1. Temperature was 99 F to 101 F, later was 103 F to 105 F, pulse in relative proportion, respirations, 30-50.

Necropsy (No 5215) was performed ten hours later. Only the pertinent findings are abstracted.

There was a generalized lymph adenopathy, the thoracic nodes being least involved. The largest mass was in the right lower abdominal quadrant. The liver and spleen were enlarged. The appendix lay retroceally, was bound down by dense adhesions, the tip had perforated into the cecum and there was a through-and-through channel from the orifice. The submaxillary glands were purulent. The fingers of

both hands, and the ears had a dry gangrene. The toes were slightly cyanotic and not gangrenous. The right hand and forearm were edematous. A calcified meningioma was in the posterior fossa. The spinal cord was not removed. One digital artery examined appeared normal.

Histology revealed Hodgkin's granuloma of all the nodes, heart, liver, spleen, adrenals, and pituitary body. The bronchial nodes were only slightly affected. The meninges had a non-specific mild granulomatous reaction.

The left common carotid, left subclavian, and right innominate arteries had a very slight atheroma. In the digital artery the lumen was narrowed. The internal elastica showed an extraordinary reduplication interspersed with extremely fine elastic fibers. The media was greatly thickened and the muscle bundles separated by fine elastic fibers. The adventitia was normal. The digital vein and nerve were somewhat fibrous and without inflammatory reaction.

Anatomic diagnoses: Hodgkin's disease of lymph nodes, spleen, liver, adrenals, heart, and pituitary body, acute bronchopneumonia, acute suppurative inflammation of submaxillary glands, remote appendicitis with appendico-colic fistula, meningioma of dura, Raynaud's disease, remote herpes zoster.

TULAREMIA IN NEW YORK STATE

FRANK N. DEALY, M.D., and ELIOT DUHAN, M.D., Jamaica, New York

THE purpose of this presentation is to remind us that this disease can occur and does exist in New York City. It further stresses the need for a careful and complete history in the recognition of tularemia.

Before January 30, 1939, no cases traced to native animals were reported in New York State. It is of interest to note that a communication received on October 7, 1939, from the New York State Health Department Division of Communicable Diseases, states: "We have encountered two instances in which tularemia was apparently contracted from wild animals in upstate New York. In the first instance, tularemia apparently was contracted from a rabbit, which was shot in the town of Wolcott, Wayne County. In the second instance, tularemia apparently was contracted from the bite of a muskrat." Francis shows that up to 1937 only 4 cases had been reported from the New England States. No case has ever been found in Vermont or Connecticut. The 3 cases below were contracted from rabbits which were imported into New York State. Investigation by the United States Public Health Service reported an increase of tularemia in the eastern states.

Case Reports

Case 1—M. J., colored female, 32 years old, was first seen in the outpatient department of the Queens General Hospital, on service of one of us (F. N. D.), at which time she had a swelling

of the left axillary region which had been incised two days previously in the emergency room. Routine dressings were applied for about four weeks. Sluggish healing prompted a more careful inquiry into the history, and the following facts were revealed:

The patient had dressed a rabbit and at the time there was present a small cut of the terminal phalanx of the left middle finger. About three days later this finger became swollen and inflamed. This infection was associated with "grippe" (generalized aches and pains, chills, and fever). The course was typical. The mass in the left axilla developed eight days later. At this time the patient went to the emergency room of the Queens General Hospital, where the mass was incised. Three weeks later nodules appeared on the forearm and patient was hospitalized. All remaining history was irrelevant.

On admission there were no systemic signs—temperature, pulse, and respirations were normal. There was a small healed scar over the terminal phalanx of the middle finger on the upper left extremity. On the extensor surface of the left arm there were small nodules about one centimeter in diameter. They were freely movable under the skin and were not tender. Subcutaneous nodules, simulating sporotrichosis, have been noted on the forearm and arms in 49 cases. In the lower anterior portion of the left axilla there was a rounded, irregular punched-out ulcer about one and a half centimeters in diameter. It was discharging yellowish purulent material. There was a hard tender mass higher up in the axilla. Right extremity showed no lesions.

The laboratory findings were white blood count 6,600, polymorphonuclear 74 per cent,

NEUROLOGIC COMPLICATIONS IN HODGKIN'S DISEASE

JAMES R. LISA, M D, New York City

(From the Pathological Laboratory, City Hospital, Welfare Island, Department of Hospitals)

THE case reported in this communication is one of Hodgkin's disease complicated by herpes zoster and Raynaud's disease. Neurologic complications in Hodgkin's disease are comparatively rare. Two distinct neurologic conditions are so unusual that it seems to justify the report of such an instance.

Case Report

The patient, a 63-year-old white woman who appeared somewhat older, was admitted to City Hospital, Medical Service of Dr. W. Laurence Whittemore, on May 22, 1939, because of fever and of pain in the fingers and toes.

There was but little pertinent information in the past history. Several years before, after her second marriage, she had been ill, the exact nature of which was unknown. In 1934 or 1935 a simple mastectomy for fibroadenoma of the right breast was performed. Roentgen examination of the chest and skeleton before operation was negative, histologic examination showed the absence of cancer.

The present illness began in July, 1937, with an attack of herpes zoster of the left chin, arm, and chest. The left axillary nodes were enlarged, the mass extending down to the breast. They continued to increase in size, seemed to fluctuate, and then regressed.

During August, burning on urination developed. A large vulvar mass was discovered and a 4 plus glycosuria, with acetonuria and a blood sugar level of 330 mg. The diabetes was quickly controlled by insulin and diet. After a few injections, further insulin therapy was refused. The glycosuria continued for about four months.

After the herpes subsided, the skin of the hands and feet became very sensitive. She complained of a sensation "as if the fingers were rough and had sand in them," and she could not perform delicate movements, such as picking up a needle. Blanching of the fingers also occurred and apparently there developed a hyperextension of the distal phalanges. Later there was a hard brawny edema with a stocking and glove distribution, stopping sharply at the ankles and wrists. The edema gradually subsided and disappeared completely by late March or early April, 1938.

Following the herpes, many attacks of profuse night sweats and acute coryza occurred. The latter appeared allergic in character. They were abrupt in onset and termination, and were accompanied by profuse nasal and lacrimal discharge.

From September, 1937, to April, 1938, she ran a fever of unknown origin. Tests for the enteric infections and Malta fever were negative.

During November, 1937, she complained of weakness, began to lose weight, and had periods when she was irrational, incontinent, and would faint after getting up.

In December, she was admitted to Queens General Hospital, from which the following data were obtained. "The patient was a short elderly woman complaining of coldness of the extremities and apparently in fair general condition. The greater part of the right breast had been removed by simple mastectomy, the transverse scar was well healed, there was no evidence of local metastases. In the right axilla were three enlarged firm nodes which felt like metastases. The right supraclavicular nodes were small and hard, the left axillary were enlarged, fairly fixed and measured 5 by 5 cm. There was one node 2 by 1 by 1 cm. in the left supraclavicular fossa. The left breast was normal. Scars of herpes were present. X-rays of the chest and skeleton failed to reveal any evidence of metastases."

FIG 1 Photomicrograph of a digital artery showing the marked reduplication of the internal elastica and the fine elastic network of the media (Low power, elastic tissue stain)

On February 10, 1938, she was admitted to another hospital presenting the clinical features suggestive of diabetic coma. Glycosuria, however, was absent and the blood sugar, N P N, and creatinine were normal. For two months she had suffered from orthopnea, cough, edema of ankles, hands, and forearms. X-rays of chest and colon were negative. Under codliver oil and yeast she improved greatly, by Easter she felt much better than she had for several months. She was discharged on April 10.

On May 22, she entered City Hospital. The most striking feature was a symmetrical dry gangrene of toes, fingers, elbows, and ears. The cervical nodes were discrete and hard. The axillary nodes were large and soft and felt cystic.

Medical News

County News

Albany County

The annual dinner of the Medical Society, County of Albany, was held on the evening of December 13 at the DeWitt Clinton Hotel. The speaker was Prof. Burges Johnson, professor of English at Union College and former editor of *Judge* and *Harper's*.

Chemung County

A resolution urging that the two existing hospital laboratories be used as a county laboratory and that a full-time health officer be placed in charge of a county health unit was adopted unanimously by members of the Chemung County Medical Society at a meeting in Arnot-Ogden Hospital on November 21.

The physicians indicated a tremendous saving for Elmira and Chemung County residents should the plan be adopted over a proposal to erect a new building or set up new laboratories.

Sixty-six of the society's 78 members attended the meeting called by Dr. Rene Breguet, president, to hear a report from a special committee composed of Dr. William T. Boland, chairman of the medical society of St. Joseph's Hospital, Dr. Arthur W. Booth, chairman of the Arnot-Ogden society, and Dr. George R. Murphy, president-elect of Chemung County Medical Society.

The committee proposed a county medical unit embracing a full-time county health officer and a complete county laboratory with services open to every citizen in the county whether a hospital patient or not. The laboratory would be in two parts, utilizing the existing hospital laboratories with slight additions to each. The work would be divided evenly.

By using the two hospitals and the existing setup both a great saving to the county and an extension of services would result, the physicians asserted.

Deputy town health officers similar to the present town health officers would be under the direction of the one head, the county health officer, and their work more thoroughly unified. The entire work of public health would thus be correlated between the city and the towns.

Clinton County

The annual meeting of the Clinton County Medical Society was held at the Witherill Hotel, Plattsburg, Tuesday, November 21. Dr. Elmer Wessell presided. The following officers were elected for 1940: president, Dr. A. B. de Grandpre, vice-president, Dr. Eric Pearson, secretary, Dr. Thomas R. Marvin, treasurer, Dr. Kenneth Clough, censors, Dr. T. A. Rogers, Dr. I. A. Rowison, and Dr. Elmer Wessell, delegates, Dr. Leo Schiff, Dr. L. G. Barton, Jr., alternate. The business meeting was followed by a dinner, after which Dr. Lyman G. Barton, Sr., delivered an address on "Medical and Surgical Practice in the 1890's."

Erie County

"The medical profession has no right to consider the question of state medicine only in terms

of its personal interests," said Dr. Terry M. Townsend, president of the Medical Society of the State of New York, speaking before the Erie County Medical Society on November 20.

"The fate of the patient is at stake," said Dr. Townsend. "State medicine is forced medicine. You'll take it and like it. It is the doctor's dole, the patient's subsidy. The patient will do what he's told, the doctor will do what he's told. And the telling will be done by an office holder who wouldn't know what to do with a patient if he had one, but thinks he can tell the specially trained man how to do what he himself cannot do."

"The patient will give up the freedom of choice of physician for the illusory benefit of medical care he may consider to be of questionable quality because he did not have to pay anything directly to get it, though by indirect taxation he will pay plenty and never know it."

Dr. Townsend urged the medical profession to take the public into their confidence, and present their views fully. "When the reasons for the doctor's opposition to state medicine are fully known," said Dr. Townsend, "the public will become aroused and refuse to submit to interference with a system which has been brought to a high state of perfection by years of effort in the public interest."

In the course of committee reports, Dr. Harvey P. Hoffman of the medical indemnity committee reported that the state insurance department, at an Albany conference, had approved the Western New York Plan, Inc., sponsored by the Erie County Medical Society, as sound. Dr. George R. Critchlow of Buffalo has been made chairman of a state committee of physicians to advise the insurance department, and Morey C. Bartholomew, the Erie County society's attorney, has been appointed to a legal advisory board.

"Ours is not only the first plan of its sort to be chartered in New York State," said Dr. Hoffman, "but is proving a guiding influence throughout the rest of the state."

Approval of a case-finding survey by means of x-ray examinations of the Negro population of Buffalo has been voted by the Health Board. The Buffalo Tuberculosis Association is to make the survey in cooperation with the Health Department.

At the same time, the board authorized establishment of a free clinic for tuberculosis diagnosis in the J. N. Adam Memorial Hospital in Perrysburg. Visitors to the hospital who request the service will be examined.

Franklin County

Dr. Wayne Henning of Stony Wold Sanatorium was the principal speaker at the regular meeting of the Saranac Lake Medical Society on November 15 in the John Black room. A large number were present. In addition to Dr. Henning, several members of his staff at Stony Wold spoke.

Fulton County

The November meeting of the Fulton County Medical Society was held on the 17th at the

lymphocytes 26 per cent, urine negative, and a positive agglutination in serum dilution of 1 320 B tularensis was obtained from the Board of Health Discharged "cured" January 27, 1936

Case 2—W K, a butcher aged 54, on December 30, 1936, while cleaning a rabbit at home "stuck himself with a broken rabbit bone" He applied the ordinary antiseptic precautions immediately to the punctured area

Except for rheumatic fever fourteen years prior, the past history was negative On December 31, 1936, he called an ambulance because he felt very sick He had a pain in the affected arm as high as the axilla The initial lesion was on the right thumb At the time he was seen by the ambulance surgeon his temperature was 105 F For the next four days he was delirious On the fifth day the patient personally incised the thumb with a pin and pus was expressed He was seen by the writer who removed a piece of rabbit bone from the thumb On the second day following the injury he noticed a large lump in his axilla The symptoms of high temperature, sweats, and a tender adenopathy in the axilla lasted for eight days During the second week of the illness he had an erythematous macular rash on his face and neck, which cleared up spontaneously in a few days

Serum agglutination for B tularensis was positive in dilution of 1 640 during the third week.

When the patient was admitted to the Queens General Hospital to service of Dr Thomas on January 28, 1937, he had a normal temperature and was not acutely ill, but his axilla was incised and yielded a yellowish purulent material The wound healed spontaneously in two months

Case 3—A S, a butcher aged 23, on January 8 1935, while cleaning a wild rabbit, accidentally punctured his right index finger with a broken bone He applied iodine and a dry dressing On January 11 he became ill, and complained of malaise, general aching pains in the extremities with fever and a slight cough His temperature was 103 F The patient was treated for influenza On January 24 he complained of a painful swelling in his right arm pit He showed a wound on his right index finger which was ulcerating A tentative diagnosis of tularemia was made

On January 25 his blood was negative for B tularensis agglutination On February 1 a positive dilution titre of 1 1,280 was found, showing that though agglutinins were slow in appearing they reached a very significant level

The node enlarged to about two and a half inches in diameter and gave evidence of ulceration By February 24 many nodes had appeared along the course of the lymphatics of the forearm, beginning at the base of the right index finger, and the patient was admitted to Mary Immaculate Hospital to service of Dr Flessa.

On February 26 an incision and drainage was performed upon the large fluctuating mass in the right axilla, and watery yellow pus was found

The patient was discharged on March 4, 1935, with a drainage wound in the right axilla

The blood examination at the hospital showed a negative Wassermann reaction, a positive agglutination reaction for B melitensis—1 320, and a positive reaction for B tularensis—1 640 The

laboratory findings revealed a negative urine, a complete blood count—red blood cells 3,670,000, hemoglobin 70 per cent, white blood corpuscles 15,000, lymphocytes 21 per cent, polymorphonuclear 78 per cent, and monocytes 1 per cent

Discussion

The 3 cases reported above illustrate the ulceroglandular type of tularemia, the most common form The other forms of this infection will not be discussed

The usual onset is sudden and manifested by headaches, vomiting, chilliness, aching through the body, and fever A few cases are ambulant throughout In most cases it is confused with influenza The primary sore at the site of infection develops as an inflamed, painful, swollen papule which suppurates leaving a punched-out ulcer about one centimeter in diameter This heals and is replaced by scar tissue Pain in the area of the lymph glands regional to the point of infection appears within two or three days after the onset The regional lymph nodes become enlarged and reddened and occasionally remain hard, but suppurate in the majority of cases The other clinical forms of tularemia, namely oculoglandular, glandular, and typhoid are less frequent in occurrence

A diagnosis is established by a history of contact with rodent or rabbit, or tick bite symptoms and physical findings An intradermal test may be done which becomes positive on the fourth day This test is as yet not generally used Agglutination by the patient's serum is positive after the tenth day and the highest titer of agglutination is reached in three or four weeks Guinea-pig or rabbit inoculation with the blood of the patient or seropus from the ulcer or the regional lymph glands results in from four to ten days in a typical ulcerative and suppurative adenopathy in the animal

One attack, as far as we know, confers lifelong immunity

Suppurative nodules and glands should be incised and drained only after suppuration is well advanced

Serum treatment as developed by Foshay has been used with good results

Keschner, W Bayard Long, Maximilian A Ramirez, Nathan Ratnof, Henry B Richardson

The New York Physicians Art Club held its annual dinner and meeting on November 16 at the Hotel Gramercy Park. Dr W Morgan Hartshorn, newly elected president, took office, succeeding Dr Stan Bauch. Plans were discussed for holding the club's annual art exhibition here next Spring, jointly with the American Physicians Art Association.

Dr John Rogers, seventy-three, surgeon and pioneer in the surgical and medical treatment of diseases of the thyroid gland, died on November 19 after an illness of several months at his home, 164 E 72nd St. He was professor of clinical surgery at Cornell University Medical College and secretary of the faculty until he retired a few years ago. He joined the faculty in 1898.

Schenectady County

At the annual meeting of the Schenectady County Medical Society on December 7, held at the Mohawk Golf Club in Schenectady, the following officers were elected for the year 1940: president, Dr F Leslie Sullivan, vice-president, Dr E MacD Stanton, secretary, Dr Joseph H Naumoff, treasurer, Dr Charles E Wiedenman, board of censors, Drs Arnaldo A Samorini, Glen Smith, William F Nealson, delegate to the State Society, Dr William C Treder, alternate, Dr Joseph H. Cornell, delegate to the Fourth District Branch, Dr Charles Rourke, alternate, Dr I Shapiro.

Monroe County

Sponsored by the Monroe County Medical Society, the Rochester Academy of Medicine and the University of Rochester School of Medicine, a public meeting on health education was held on November 26 at the Academy of Medicine.

Dr Charles Gordon Heyd of New York City, former president of the American Medical Association, spoke on "The Romance of Modern Surgery." Also on the program was the premier showing of a new sound movie, "Man against the World." The picture told the story of surgery's inception in 1852 with the first major abdominal operation.

Montgomery County

Dr William R. Pierce, one of the oldest practitioners in Amsterdam, died at his home there, on November 2. He was secretary of the Montgomery County Medical Society.

Nassau County

At the meeting of the Nassau County Medical Society on November 28, the speaker was Henry Clans Sweany, M D, Medical Director of Research, Chicago Municipal Tuberculosis Sanatorium, and the topic "What the Doctor Should Know about Tuberculosis." A modern version of an old story.

St. Lawrence County

Annual election of officers and meeting of the St. Lawrence County Medical Society was held on November 2 at the Arlington Inn at Potsdam with over fifty present. The principal speaker was Dr John Free, Ogdensburg, who gave an illustrated lecture on chest surgery.

Dr David M Mills, Gouverneur, was named president of the society to succeed Dr Jay E Meeker, Ogdensburg. Other officers are Dr U R Plante, Massena, vice-president, Dr Robert J Reynolds, Potsdam, secretary, Dr S W Close, Gouverneur, secretary emeritus, Dr Lloyd T McNulty, Potsdam, treasurer, Dr P G Taddiken, Ogdensburg, Dr C F Prairie, Massena, and Dr M J Stearns, Ogdensburg, censors. Delegate to the house of delegates for 1940-1941 is Dr W H Mulholland, Heuvelton, and Dr S W Sayer, Gouverneur, alternate. Dr Free is delegate to the district branch and Dr Prairie, Massena, alternate.

Suffolk County

Dr William H Ross was guest of honor at a dinner given by the Suffolk County Medical Society on Saturday evening, November 25, at Smithtown in recognition of his fifty years in the practice of medicine.

Richly deserved tributes were paid Dr Ross by Dr Terry Townsend, president, and Dr Peter Irving, secretary and manager of the New York State Medical Society, Dr Alec Thomson, secretary of the Kings County Medical Society, Dr Frank Overton of the *New Jersey State Medical Journal*, Dr Arthur D Jaques of Lynbrook, president of the Associated Physicians of Long Island, and Dr Willets Gardner, president of the Suffolk County Medical Society.

"His fame," said Dr Townsend, "is richly deserved—the fame of well-doing."

Dr Gardner enumerated the various offices held by Dr Ross.

President Medical Society, State of New York, Associated Physicians of Long Island, Suffolk County Medical Society, N Y Association of Superintendents and Managers of Tuberculosis Sanatoria, Suffolk County Tuberculosis and Public Health Association, Southside Clinical Society, Board of Managers, Suffolk Sanatorium.

Trustee Medical Society, State of New York, Chairman Suffolk County Board of Health, Suffolk County Mosquito Commission, Medical Board, Southside Hospital.

Dr Gardner then introduced the next speaker, Dr Peter Irving. Dr Irving said, in part, "Across fifty years has marched a sturdy soldier of the army of private practitioners, I want to congratulate the Society for having the interest of such a man." Said Dr Irving "I wonder how, in addition to all the public offices he has held, he could find time to be a private practitioner. Dr Ross has done his work well."

The 134th Annual Meeting of the Suffolk County Medical Society was held at the Huntington Crescent Club, Wednesday, November 1. The following officers were elected: president, John Sengstack, Huntington, first vice-president, George Bergmann, Mattituck, second vice-president, David Corcoran, Central Islip, secretary, Edwin P Kolb, Holtsville, treasurer, Grover A. Sillman, Sayville, censors, Paul Nugent, Leon Barber, Louis Garben, George Thompson, and Cyril Drysdale, delegates to State Society, John Sengstack and Coburn Campbell, delegates to 2nd District Branch, David MacDonnell and Earl McCoy.

At the scientific session, valuable information on the Workmen's Compensation Law was given

Hotel Johnstown with Dr John A Shannon, presiding

A short business session was held followed by a talk by Dr Joseph S Lawrence, executive officer of the New York State Medical Society

Dr Lawrence devoted his address to "Socialized Medicine" He emphasized the fact that there is one doctor to every 500 people residing in the state, also one hospital bed for every group of 259 residents Dr Lawrence pointed out that throughout the entire state, there isn't a person who isn't living within one-half hour's distance from either a physician or a hospital

Kings County

Life insurance was the topic at the meeting of the Medical Society of the County of Kings on November 21 Addresses were delivered as follows

"Savings Bank Life Insurance and Doctors," Cornelius V Coleman, Brooklyn

"Organized Dollars at Your Command Pertinent Suggestions for Doctors on Making the Best Use of Their Life Insurance," Benjamin Alk, C L U, Manhattan, President, The Life Underwriters' Association of the City of New York

"Establishing an Economic Program," J Arthur Buchanan, M D, Brooklyn, Chairman, Economics Committee, Medical Society of the County of Kings

The tenth clinical meeting of the Brooklyn Thoracic Society was held at the Kings County Hospital on November 24 Dr William H Field, Dr Henry Louria, Dr Herbert Maier, and Dr Harry Reibstein, took part in the "Symposium on Empyema" Discussion was opened by Dr Edwin J Grace.

Madison County

At the 133rd annual meeting of the Madison County Medical Society, in Oneida, Dr E T Centerwall, Morrisville, was elected president He succeeds Dr Ernest Freshman, Oneida, who was named delegate to the State Medical Society meeting next May

Other officers are Dr Howard Beach, Oneida, vice-president, Dr Lee S Preston, Oneida, re-elected secretary, and Dr Paul Ferrara, Canastota, treasurer The board of censors includes Dr E H Carpenter, Dr Otto Pfaff, Oneida, and Dr O S Langworthy, Hamilton.

The program consisted of election of officers followed by papers, as listed

"The Medical Care of County Welfare Patients," by Lee C Dowling, Deputy Commissioner, New York State Welfare Department, Albany

President's address, "Albuminuria in Children," Dr Ernest Freshman. "Peripheral Vascular Disease," Dr Arthur N Curtiss, Syracuse Illustrated by slides

"Pneumonia—Diagnosis and Treatment," Dr Henry V Hyde, Syracuse.

Onondaga County

The Syracuse Academy of Medicine had as the features of its meeting at the University Club on December 10, three case reports "Report of a Case of Trachoma" by Dr James F Cahill, "A Case of Complete Placenta Praevia" by Dr C W Kenney, and "The Use of Vitamin K in Jaundice" by Dr Geo S Reed

At the meeting of the Obstetric Society of the Syracuse hospitals, held Tuesday, November 14, at the College of Medicine, the following resolution was passed

WHEREAS, it has been found that maternal deaths as a result of criminal abortion are a constant factor in maintaining the present high maternal mortality rate,

Be It Resolved, that the members of the Obstetric Society of the Syracuse hospitals investigate each case of criminal abortion which comes to their attention and report to the District Attorney the evidence and names of each person or persons involved, and cooperate to the fullest extent in the legal prosecution of those concerned.

Orange County

The annual meeting of the Orange County Health Association was held at the Storm King Arms, Cornwall-on-Hudson, on November 8, when Dr Roswell L Schmitt of Middletown was elected president He succeeds the Rev Dr Forest P Hunter, also of Middletown, who has headed the association for many years

Queens County

In the largest turnout in the history of the Queens County Medical Society, Dr Thomas d'Angelo, of Jackson Heights, was chosen president-elect over Dr Jacob Werne of Jamaica, on November 28 Other officers elected were secretary, Dr Chester L Davidson, assistant secretary, Dr Abraham Braunstein, treasurer, Dr Bernard Davidoff, assistant treasurer, Dr Samuel M Klein, historian, Dr W Guernsey Frey, directing librarian, Dr William Benenson, assistant directing librarian, Dr Elmer Kleefeld, delegates, Drs James R Reuling and Joseph Wrana, alternates, Drs Thomas d'Angelo, James Dobbins, and Jacob Werne, trustees, Drs Henry C Eichacker, Frank R. Mazzola, Goodwin Distler, and Joseph Wrana

The censors are Dr Joseph Lanza, first district, Dr John Keating, second district, and Dr David Lothringer, sixth district. Dr Amedeo DePoto was elected censor-at-large.

New York County

The 134th annual meeting of the Medical Society of the County of New York was held at the New York Academy of Medicine on November 27 These officers were elected for the ensuing year

President-elect, Alfred M Hellman, first vice-president, Maximilian A Ramirez, second vice-president, Vincenzo Fanoni, secretary, B Wallace Hamilton, assistant secretary, William L Wheeler, Jr, treasurer, Kirby Dwight, assistant treasurer, Howard Patterson, Censors (for three years), Conrad Berens, Francis N Kimball, (for two years) Samuel B Burk, chairman, Committee on Legislation, Arthur M Master, chairman, Committee on Public Relations, Ernst P Boas, chairman, Committee on Medical Economics, Bernard S Denzer, chairman, Committee on Membership, Alfred G Forman, trustee (for five years), Howard Fox.

Delegates to the Medical Society of the State of New York (for two years) Walter P Anderson, George Baehr, Emily D Barringer, Edward K. Barsky, Vincenzo Fanoni, Howard Fox, Benjamin Jablons, Samuel M Kaufman, Moses

Keschner, W Bayard Long, Maximilian A Ramirez, Nathan Ratnof, Henry B Richardson.

The New York Physicians Art Club held its annual dinner and meeting on November 16 at the Hotel Gramercy Park. Dr W Morgan Hartshorn, newly elected president, took office, succeeding Dr Stan Bauch. Plans were discussed for holding the club's annual art exhibition here next Spring, jointly with the American Physicians Art Association.

Dr John Rogers, seventy-three, surgeon and pioneer in the surgical and medical treatment of diseases of the thyroid gland, died on November 19 after an illness of several months at his home, 164 E 72nd St. He was professor of clinical surgery at Cornell University Medical College and secretary of the faculty until he retired a few years ago. He joined the faculty in 1898.

Schenectady County

At the annual meeting of the Schenectady County Medical Society on December 7, held at the Mohawk Golf Club in Schenectady, the following officers were elected for the year 1940: president, Dr F Leslie Sullivan, vice-president, Dr E MacD Stanton, secretary, Dr Joseph H Naumoff, treasurer, Dr Charles E Wiedenman, board of censors, Drs Arnaldo A Samorini, Glen Smith, William F Nealon, delegate to the State Society, Dr William C Treder, alternate, Dr Joseph H Cornell, delegate to the Fourth District Branch, Dr Charles Rourke, alternate, Dr I Shapiro.

Monroe County

Sponsored by the Monroe County Medical Society, the Rochester Academy of Medicine and the University of Rochester School of Medicine, a public meeting on health education was held on November 26 at the Academy of Medicine.

Dr Charles Gordon Heyd of New York City, former president of the American Medical Association, spoke on "The Romance of Modern Surgery." Also on the program was the premier showing of a new sound movie, "Man against the World." The picture told the story of surgery's inception in 1852 with the first major abdominal operation.

Montgomery County

Dr William R. Pierce, one of the oldest practitioners in Amsterdam, died at his home there, on November 2. He was secretary of the Montgomery County Medical Society.

Nassau County

At the meeting of the Nassau County Medical Society on November 28, the speaker was Henry Claris Sweany, M D, Medical Director of Research, Chicago Municipal Tuberculosis Sanatorium, and the topic "What the Doctor Should Know about Tuberculosis." A modern version of an old story.

St. Lawrence County

Annual election of officers and meeting of the St. Lawrence County Medical Society was held on November 2 at the Arlington Inn at Potsdam with over fifty present. The principal speaker was Dr John Free, Ogdensburg, who gave an illustrated lecture on chest surgery.

Dr David M Mills, Gouverneur, was named president of the society to succeed Dr Jay E Meeker, Ogdensburg. Other officers are Dr U R. At the scientific session, valuable information on the Workmen's Compensation Law was given.

by Dr David Kaliski, of the State Society, and Dr S G Feuer, Representative of the Insurance Carriers on the Arbitration Board

Warren County

Early diagnosis and active intelligent treatment of cancer is the best treatment and one that gives the greatest results, Dr Charles F Geschickter of Baltimore, Md., declared in an address before the Glens Falls Academy of Medicine on November 24 at the Crandall Library. Dr

Geschickter's subject was "Malignancies of the Breast."

Dr Stanton, of Schenectady, opened the discussion by presenting a series of cases which he followed from 1907 to 1926, from the time of operation for cancer and through death. Other physicians who discussed Dr Geschickter's comments were Dr Cummings of Ticonderoga, Dr Irving R Juster, Dr A W Chapman, Dr E B Probasco, Dr Morris Maslon of Glens Falls, and Dr Felix Schrenck of Chestertown.

THE DOCTOR'S WIFE

A few weeks ago Dr Rock Sleyster, president of the A M A, addressed the Woman's Auxiliary of the Wisconsin State Medical Association, meeting in Milwaukee, on this interesting subject. He said in part:

"After an experience of some thirty-six years as the husband of a doctor's wife I am appreciative of the fact that no single influence helps to develop and mold the doctor as does his nearest partner in the business and adventure of life. The development of character, of personality, of standards, of ideals, of humanness depends upon her influence as upon no other. And his success and influence in his community depend upon these qualities as much as upon his scientific attainments.

"Nothing—and I say this without the slightest mental reservation—*nothing* is as important in shaping the doctor's career as are his wife and his home. The doctor's wife must share his idealism, appreciate a standard of values held by no other group, and give to him an understanding required of few. Being a doctor's wife is both an art and a career.

"There are many temptations in his professional career which must be met. There is with need at times the temptation to commercialism. With fatigue, there is the urge for relaxation and amusement, at the expense of necessary reading and study that he may bring all that is new to

the bedside of the sick. There is the temptation to be truant to the meetings of his medical organizations for these same reasons. There is the urge to retaliate and strike back at fancied or actual wrongs at the hands of his colleagues.

There is the opportunity to advance at the expense of others by unfair advantage. In all of these, and in many other circumstances, the temptation will be as great to his wife as to the doctor. She will want material rewards, more rest for him, more of his time and companionship—even more than he—and her whole inclination will be to fight fiercely in his defense. But this cannot be, hers must be the influence to keep his aim at the stars, his purpose unchanged, his ideals in no way lowered, and his character outstanding and above reproach.

"But when the autumn days are here, and the task must be lightened, you will be standing with him in the twilight, as he passes on to younger hands the glory of a professional career above reproach, a career perhaps without material reward but a career good and clean and true to all the teachings of a great physician who came to us from Galilee. And as you stand hand in hand and look back over the years, there will be the joy and satisfaction of hearing him say—'You were my partner—it was possible only because of you.'"

Medicolegal

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Two Interesting Wills

THE article of the Penal Law of the State of New York entitled "Sepulture" has for many years provided that an individual has the right to direct the manner in which his body shall be disposed of after death. Recently two proceedings dealing with the interpretation of that principle have been brought before the surrogates of different counties in New York City, and the manner in which those courts dealt with the problems presented is of interest.

In the first case,* the petitioner sought to have admitted to probate documents purporting to be a will and codicil which had been executed with the usual technical formalities by one M. J. as testatrix. The material provisions were to the effect that the testatrix "being of sound mind and in full possession of my senses and for no thought of remuneration but purely out of the largeness of my heart and a keen desire to help, if possible, the cause of science, do hereby bequeath my body for the purposes of medical research. Such research is to be conducted under the direction, either jointly or singly of J. A. C.—M. D., and H. A.—M. D., at present both of the City of New York and the Harkness Pavilion. It is my wish that my body be cremated in the simplest form and without grass."

The court in the case reviewed numerous older authorities and concluded that the papers in question should be admitted to probate as the will of M. J.

The surrogate stated in his opinion as a preliminary proposition:

Probate courts do not exclude from an admitted instrument matter which is itself not dispositive provided the instrument otherwise contains dispositive provisions or provides for the appointment of an executor. The views of testators on mundane and celestial affairs (so long as not libelous or scandalous) are ordinarily recorded as part of the testamentary instrument. The courts decline, however, to probate instruments which contain neither dispositive provisions nor executorial appointment. The question presented by this petition and by the tender of the instruments now before the court is whether a paper purporting to dispose of a dead body only is a testamentary instrument and hence entitled to probate."

The question of the right to make directions as to the disposition of one's body by will was discussed in part as follows:

"There was an outpouring in the nineteenth century of court decisions on the question of whether there is any property in a corpse. This was the outcome mainly of three distinct and unrelated causes. As a result of loosened family ties it sometimes happened that a man's widow

and 'next of kin' contested for the control of the deceased's body for purposes of burial. The courts were obliged to consider whether there are rights in or to a corpse and whether a corpse is in any sense property. The rise of medical schools, the increase in the number of doctors and the recognition in medical circles of the need for knowledge of the human body based on the art of dissection resulted in unauthorized autopsies, and body-snatching from graveyards. (Parenthetically it may be noted that this factor in one celebrated instance occasioned the development of a business in homicide carried on by two enterprising murderers named Burke and Hare who, obeying the law of supply and demand, provided eager doctors with what they greatly needed but could not legally obtain in sufficient quantity. It was thus that the verb 'to burke'—meaning to kill by suffocation—entered our language.) Unauthorized dissections of dead bodies resulted in suits for damages by aggrieved next of kin and the courts were obliged to determine whether there was property in a dead body. Lastly, interment ceased gradually to be the universal method for disposing of the dead. When testators directed cremation of their remains some of their next of kin, out of religious or other considerations, challenged the right in the deceased to direct that such disposition should be made of his corpse."

"For these reasons a considerable body of case law developed. The majority of the courts plainly held that a testator might use his will to give binding directions respecting the disposition of his remains."

In conclusion the court stated:

"Historically she has performed an act of testamentation giving directions respecting her body. Since the directions contravene no statute and are consistent with the proprieties there is no reason why the directions may not be given effect. Specifically there is no reason why the instrument may not be probated as a means of giving effect to her wishes."

The situation presented in the second proceeding was somewhat different.† The decedent had died leaving a will and two codicils which were duly admitted to probate. They provided in addition to directing the manner of disposing of her possessions that the sum of \$1,200 should be expended for the purpose of transporting her body to Palestine, and for burial there. It seems that at the time of her death the children, being in ignorance of these directions, had caused her interment in a cemetery in this state, spending for the purpose about \$200.

Upon an accounting proceeding, the distributees of the estate unanimously sought the approval of the surrogate to leaving her remains undisturbed. Certain affidavits were submitted, two of which were by rabbis (the deceased being

* Matter of Johnson. 169 Misc. 215.

† Matter of Scheck. 172 Misc. 238.

of the Jewish faith) to the effect that to disinter the body and remove it to Palestine would be contrary to Jewish tenets and Hebrew laws. The affidavits of certain members of the family tended to prove that at the time the testamentary instruments were drawn the decedent was living in Palestine and making payments on a burial plot in that country. It was shown that she subsequently left Palestine, returned to this country, discontinued the said payments, and instead started payments on the burial plot in which her remains were actually placed. She was said by those relatives to have before her death expressed wishes to be buried in the latter plot.

The surrogate in this case, while recognizing the right of an individual to dispose of his body by will, determined that since such a testamentary provision is not a disposition of actual "property" it could be refuted in a proper case by outside proof in a manner in which testamentary provisions concerning the disposition of monies, for instance, could not be refuted.

In so deciding the surrogate said in part in his opinion:

"a direction in a will respecting disposal of the body of the testator is not testamentary in character to a degree which would require revocation of the direction to be accomplished in the manner prescribed in section 34 of the Decedent Estate Law. As noted, a dead body is not properly viewable as property or assets, and since time immemorial it has been the settled law in all common-law jurisdictions that a will is 'the affirmative expression of intent of the testator respecting the administration and disposition of his material possessions upon his death'."

The surrogate stated that a direction concerning disposition of the body of a deceased person "is not testamentary in character and is not in any particular, either as to initial insertion, or subsequent revocation, to be governed by the ordinary rules relating to strictly testamentary directions. An inevitable sequence of this conception is the right of a particular decedent, from time to time in his discretion, to vary the directions respecting disposal of his remains, with the result that the inquiry of the court must be directed to the ascertainment of the latest expression of wish by the testator on the subject."

Retained Secundines

A WOMAN thirty years of age, having previously been delivered of one child, consulted an obstetrician in her eighth month of pregnancy and made arrangements for him to care for her confinement and delivery. Examination showed the condition of the patient to be in all respects normal and upon subsequent examination, three or four weeks later, her condition again was satisfactory.

The next time the doctor saw the patient a vaginal examination showed that the patient was two fingers dilated and that the head was engaged. The patient was not in labor. After further examination the physician concluded that the woman had a uterine inertia and that induction was needed to start labor.

The patient was hospitalized and the first stage of labor began the following day, lasting about five hours. Shortly thereafter the physician determined that a forceps delivery was indicated and performed an episiotomy and with low forceps delivered a normal female child. The placenta was expelled and upon examination both by the doctor and by the assisting nurse it appeared to be intact. After delivery the patient ran a normal course and left the hospital in eleven days.

It seems that about a week following the return of the patient to her home, she called another physician who found her suffering from vaginal bleeding, which developed into a profuse hemorrhage. Said physician took the woman to a hospital where a diagnosis of retained secundines was made and a dilatation and curettage was done, removing some pieces of placental tissue. A blood transfusion was administered. Following this the patient promptly regained her health.

A malpractice action was instituted on behalf of the patient charging that the defendant doctor had so negligently conducted himself in delivering the plaintiff that he improperly caused certain portions of placental tissue to remain within her body, causing her to sustain severe injuries.

The case was placed upon the calendar for trial but never actually brought to trial by the plaintiff's attorney, and was finally terminated by a motion to dismiss for lack of prosecution, which was granted by the court.

DICKENS AND THE DOCTORS

A book is out on *Doctors, Nurses and Dickens*, by Robert D. Neely, published in Boston by the Christopher Publishing House, in which the author has selected those passages from Dickens' books which treat of medicine, the doctor and his variety of assistants, such as nurses, interns, students, and finally undertakers. It is not only a pleasant intermezzo of medicine as studied by Dickens in relation to all strata of society but a delightful picture of Dickens' own life, troubles and vicissitudes, says the *New England Journal of Medicine*. To one who reads the book it will give not only a most pleasant and warm evening but considerable food for thought.

For instance, the sayings of Esther Summerson, the heroine of *Bleak House*, after her marriage to Dr. Allan Woodcourt, show in what high regard Dickens held the medical profession. She says "I never walk out with my husband, but I hear the people bless him. I never go into a house of any degree, but I hear his praises, or see them in grateful eyes. I never lie down at night, but I know that in the course of that day he has alleviated pain, and soothed some fellow-creature in the time of need. I know that from the beds of those who were past recovery, thanks have often, often gone up in the last hour, for his patient ministrations. Is not this to be rich?"

The Woman's Auxiliary

To the Medical Society of the State of New York

County News

Cayuga County

The Woman's Auxiliary held its annual meeting December 14 at the Osborne Hotel. The following officers were elected: Mrs G C Sincerbeaux, president, Mrs J D Sands, first vice-president, Mrs W L Dorr, second vice-president, Mrs S J Karpenski, recording secretary, Mrs W H Havill, corresponding secretary, Mrs F L Okoniewski, treasurer. At the close of the short business meeting, the auxiliary members joined the members of the Medical Society for a Christmas dinner party. The guest speaker of the evening was Dr Milledge I Bonham, Jr, professor of history at Hamilton College, Clinton, New York, whose subject was "American-Canadian Relations."

Columbia County

At the annual meeting of the Woman's Auxiliary the following officers were elected: president, Mrs W D Collins, Hudson, president-elect, Mrs R L Bowerhan, Copake, first vice-president, Mrs H A Pattison, Livingston, second vice-president, Mrs L J Shank, Kunderhook, recording secretary, Mrs C F Nichols, Philmont, corresponding secretary, Mrs O H Bradley, Hudson, treasurer, Mrs H G Henry, Germantown. Following the business meeting a card party was held. A portion of the proceeds was sent to the Physicians' Home.

Fulton County

On November 21, at the Hotel Johnston, Johnston, New York, the Woman's Auxiliary was organized. Every part of the county was represented at the dinner preceding the meeting. The following officers were elected: president, Mrs B G McKillip, Gloversville, president-elect, Mrs J E Grant, Northville, first vice-president, Mrs J Shannon, Johnstown, second vice-president, Mrs W R Gruenwald, Mayfield, secretary, Mrs B E Chapman, Broadalbm, treasurer, Mrs W Kennedy, Gloversville, corresponding secretary, Mrs B A Winne, Johnstown.

The first regular meeting of the new auxiliary was held December 21.

Kings County

The Kings County Woman's Auxiliary held a benefit bridge party in December at the homes of Mrs Fisher and Mrs Beinfield. The proceeds of the affair were donated to the Physicians' Home.

Onondaga County

The Woman's Auxiliary to the Onondaga County Medical Society held its annual meeting in December at the home of Mrs F J O'Connor. Annual reports were read by officers and committee chairmen. The following officers were elected for the coming year: president, Mrs E M Neptune, vice-presidents, Mrs W W Street and Mrs L E Gibson, recording secretary, Mrs G C Murdock, corresponding secretary, Mrs J G Derr, assistant corresponding secretary, Mrs R E Fenner, directors, Mrs W Pennock, and Mrs Francis Irving.

Orange County

The Woman's Auxiliary held its annual luncheon meeting December 6 at Middletown, New York. Reports given by each chairman of standing committees showed that it had been a very active year, the high light being the Health Institute held in May. New officers elected for the coming year were: president, Mrs F W Seward, Goshen, president-elect, Mrs H F Murray, Port Jervis, vice-president, Mrs J W McKeever, Newburgh, recording secretary, Mrs C S McMillan, Newburgh, treasurer, Mrs J F Ross, Montgomery.

Schenectady County

The Woman's Auxiliary recently held a luncheon and bridge party at Newman's Lake House, Saratoga Lake. Mrs G Scott Towne, State Auxiliary president, was the guest of honor.

"THE NATURE OF OBESITY"

The Cornell Medical College chapter of Nu Sigma Nu fraternity is sponsoring a lecture entitled "The Nature of Obesity" to be presented in the auditorium of the Cornell Medical College on Wednesday, December 13, at 8 00 P.M. by Dr David P Barr.

Dr Barr, Professor of Medicine at the Washington University School of Medicine in St. Louis, is a well-known authority in the field of endocrinology.

The lecture will be open to all those interested.

YIELDING TO THE MAJORITY

A Philadelphia physician, in declaring that insanity was frequently productive of sound logic tempered with wit, told the story of a patient he once met in an asylum.

He came across this patient while strolling through the grounds, and, stopping, spoke to him "Why are you here?"

"Simply a difference of opinion," replied the patient. "I said all men were mad, and all men said I was mad—and the majority won"—

RECEIVED

A Guide to Workmen's Compensation. The Law and Its Practice in New York State By H D Margulies and Max Bloom Duodecimo of 96 pages New York, Progress Books, 1939 Paper, \$0 50

This guide, written by H D Margulies and Max Bloom, labor attorneys practicing before the Workmen's Compensation Board, offers to the physician in brief form a convenient and comprehensive source of information regarding the medicolegal aspects of the law of Workmen's Compensation

Physicians authorized to treat injuries resulting from industrial accidents, need a quick guide for determining whether a particular case is compensable This, as we know, determines the liability of the employer or his carrier for the payment of medical fees

Information on these and other topics can be found in the sections entitled "Occupations Covered," "Medical Treatment and Care," "Schedule Losses," "Occupational Diseases," "Practice and Procedure," "Medical Evidence," and "Selected Rules for Physicians"

As a first guide on workmen's compensation in the State of New York, this book fills a long-felt need for a popular interpretation of a highly specialized study It is very handy and useful in compensation work

SAMUEL M KAUFMAN

Psychopathic States. By D K Henderson, M D Octavo of 178 pages New York, W W Norton & Co, Inc, 1939 Cloth, \$2 00

This volume includes the Thomas W Salmon Memorial Lectures given in 1938 by Dr Henderson, who is professor of psychiatry at the University of Edinburgh, and physician-superintendent of the Royal Edinburgh Hospital for Nervous and Mental Disorders

The author brings into these lectures a wealth of practical experience in studying and treating varying degrees of psychopathic states, both in the United States and abroad When one considers the widespread social disruption caused by this type of social deviate, Dr Henderson has rendered a signal service not only to the medical profession, but to society in clarifying the problems and needs of this most perplexing disruptive member of our social order

In a scholarly fashion Dr Henderson interprets the term "psychopath" and suggests a practical classification of different types These are well illustrated by critically selected case histories The work is divided into three chapters Place in Psychiatry, Clinical Manifestations, and Social Rehabilitation It is rounded out with pertinent references and an adequate index

This book is of inestimable import, and should be within arm's reach of every psychiatrist, as

well as psychologist, social worker, sociologist, penologist, educator, and intelligent layman.

FREDERICK L PATRY

Practical Dermatology and Syphilis By Harry M Robinson, M D Octavo of 397 pages, illustrated Philadelphia, P Blakiston's Son & Co, 1939 Cloth, \$4 50

Doctor Robinson has succeeded in producing the most concise, most up-to-date and best illustrated handy volume on his subjects that it has been our pleasure to examine in many a day Few of the larger works on dermatology and syphilis can boast of more instructive or elucidative illustrations than the 439 which he has selected with great care to help the student and to assist the busy general practitioner in making his diagnosis

This is a new book of practical procedures for the diagnosis and treatment of the commoner skin diseases and syphilis Clinical diagnosis is taught from two standpoints the morphology of primary and secondary lesions, and their distribution The simplification of dermatologic nomenclature is aided by listing such clinical syndromes as urticaria, erythema multiforme, pityriasis rubra, eczema, rosacea, etc, as clinical or diagnostic entities

Dr Robinson is to be congratulated on the preparation of a work which sets a standard for other authors to emulate. The reader is presented with a most comprehensive atlas of excellent pictures and a description of the etiology, differential diagnosis, and latest approved treatment for each disease

NATHAN T BEERS

Doctor, Here's Your Hat! The Autobiography of a Family Doctor By Joseph A Jerger, M D Octavo of 279 pages New York, Prentice-Hall, Inc, 1939 Cloth, \$2 75

The title of the book finds its explanation in the feeling of the author that "superspecialism" is handing the family doctor his hat and showing him the door The subtitle might more appropriately be worded, "the autobiography of a general specialist," as the doctor calls himself on signing a contract with the landlord of his new apartment, after he finally arrives professionally in Chicago

This book is the biography of a man whose personal and medical history is well beyond the ordinary Born in England, visiting many strange places as a boy, taken early in life to live in Australia, he comes to America to study medicine at the suggestion of Mark Twain, whom he meets on a voyage from South Africa to England He becomes an American citizen. After an internship in Chicago, with the assistance of Dr Nicholas Senn, he enters into a partnership with "Old Doc" Fullerton in Waterloo, Iowa

Dr Fullerton is a successful country practitioner

and evidently not only a good doctor but a fine character. He is given ample credit for the training and development of his assistant. Under the tutelage of his wise and capable preceptor, the author lives a busy and profitable life as a general practitioner with a rapidly developing aptitude for surgery. He tells many interesting tales. As might be expected, many of the reported cases illustrate the intuition and diagnostic sagacity of the general practitioner and the befuddlement of the superspecialist. We will say for the author that wherever he went, he went to learn, and so his knowledge is exceptional.

While working with "Old Doc" Fullerton, the importance of the clinical aspects of a case is stressed. Later in the book, he introduces a three-page dissertation on approved modern methods of diagnosis and treatment. That these methods are not always 100 per cent efficient, and that their overemphasis may lead to superspecialism and occasional abuse in no way nullifies their help to the patient as well as to the doctor. The author's discussions of the economic, social, and ethical aspects of medicine would naturally follow in a book with such a title.

JOSEPH RAPHAEL

Everyday Surgery. By Lambert Rogers, F.R.C.S., and A. L. D'Abreu, F.R.C.S. Octavo of 280 pages, illustrated. Baltimore, William Wood & Co., 1938. Cloth, \$4.75.

This small volume provides an excellent summary of surgical procedure for the student preparing for examination, but its value to the surgeon is less evident.

As exponents of everyday surgery, the authors include all subjects excepting only diseases of women, and those of the eye, ear, nose, and throat. All other surgical procedure is covered in 266 pages, and discussion of clinical features and other detail is of necessity quite brief.

Within their limited space the authors have produced a volume useful and interesting to those for whom it was written. The type is clear and the book of convenient size for reading.

STANLEY B. THOMAS

Chemistry in Relation to Biology and Medicine with Especial Reference to Insulin and Other Hormones. The Willard Gibbs Lecture by John Jacob Abel. Octavo of 79 pages. Baltimore, The Williams & Wilkins Co., 1938. Cloth.

This beautifully printed little volume is a worthy tribute to Professor Abel and to the publishing house, the impress of which it bears. Dr. E. K. Marshall contributes an introduction to the Willard Gibbs Lecture of 1927, which constitutes the body of the book. In this he discusses briefly Dr. Abel's many contributions to medical sciences, and enumerates many of the collaborators who distinguished themselves by working with this great investigator. In 1909, when he founded the *Journal of Pharmacology and Experimental Therapeutics*, Dr. Abel was instrumental in starting the medical publication division of The Williams and Wilkins Company, which has since had a splendid career as one of several great medical publishing houses to which the American medical profession is con-

stantly indebted. Nothing further need be said regarding the Gibbs Lecture itself, which has a secure niche in medical history. It will repay rereading.

MILTON PLOTZ

The Abnormal in Obstetrics. By Sir Comyns Berkeley, M.D., Victor Bonney, M.D., and Douglas MacLeod, M.B. Octavo of 525 pages. Baltimore, William Wood & Co., 1938. Cloth \$6.00.

These three well-known English authors have enriched our obstetric literature by including in one small volume the entire range of obstetrics, commencing with sterility, the hormones, and the disorders of every tissue and organ that are likely to occur during pregnancy, to all complications of labor and the puerperium. There are special chapters on diseases and injuries of the newborn, blood transfusion and other intravenous therapy, analgesia and anesthesia, specific affections and contagious diseases, and mental disorders associated with childbearing.

Bleedings and infections, the most frequent and dangerous complications in obstetrics, are exhaustively covered. The authors' views are conservative, authoritative, and timely. They conform well to the best views on this side of the ocean.

Naturally, some of the methods employed in England are not in vogue in this country, for example, intrauterine douching for postpartum hemorrhage is stressed as an excellent measure, and is mentioned repeatedly in several chapters. On the other hand, intrauterine packing for the same condition is not advised. Vaginal douching, daily or at less frequent intervals, is advised in all forms of postpartum infections.

With the exception of a few simple line drawings depicting the technic of transfusion, the book is not illustrated.

Indeed, if it were not for that, it would have been well nigh impossible to cover such an extensive range of subjects and pack so much valuable information in a small volume.

The book is highly recommended, not only to those actively engaged in obstetric practice, but even to those who have only on occasion to refer to some subject relating to it.

JACOB HALPERIN

Orthopedic Appliances. *The Principles and Practice of Brace Construction for the Use of Orthopedic Surgeons and Bracemakers.* By Henry H. Jordan, M.D. Octavo of 412 pages, illustrated. New York, Oxford University Press, 1938. Cloth, \$4.00.

The need for such a text was imperative for the orthopedist. While books on orthopedic surgery, traumatic surgery, and fractures give a slight glimpse into the mechanical phase of supporting the distorted framework of the human body, this author describes in detail the fitting of braces and supports to the deformity present. Emphasis is placed on the need of brace shop training (apprenticeship) as a fundamental need in orthopedic surgery.

The first four chapters are devoted to the use of the plaster of Paris bandage and the making of plaster molds for spinal and low-back defects. From these molds the various types of corrective and supportive appliances are fashioned.

according to the dictates of the attending orthopedist. Too often the application of a support or brace is left in the hands of the brace-maker who does not understand the underlying mechanical defect and pathology, but rather is interested in the financial remuneration to be received by the addition of unnecessary gadgets and details of completion.

The basic requirements for efficient brace making is discussed, viz (1) correct medical indication, (2) scientific brace construction, (3) good workmanship, (4) high grade material, (5) careful fitting, and (6) intelligent use by the patient.

The names of all the important appliances and braces are given, illustrated, and described in detail, so that there is no doubt in the brace-maker's mind what the orthopedist wishes prescribed.

A knowledge of the contents of this book is helpful in the better caring for the physically handicapped.

JOSEPH I NEVINS

Whitla's Dictionary of Treatment. Including Medical and Surgical Therapeutics Eighth edition by R. S. Allison, M.D., and C. A. Calvert, M.B. Octavo of 1,285 pages. Baltimore, William Wood & Co., 1939. Cloth, \$9.00.

This volume of nearly 1,300 pages of both medical and surgical conditions with treatment is a useful book for reference. Subjects and diseases are alphabetically given and the treatment is that of the present time. It is inclusive, well written, and accurate. This type of publication is not valuable as a book of instruction or as a textbook, but can be advantageously used for reference.

HENRY M. MOSES

A Synopsis of Medicine. By Henry Letheby Tidy, M.D. Seventh edition. Duodecimo of 1,187 pages. Baltimore, William Wood & Co., 1939. Cloth, \$6.00.

Seven editions and three reprinting demands for this useful synopsis and presentation of the subject of medicine attests the value of this book. So rapid has been the advance in the science of medicine that this seventh edition has had many additions incorporated—too many to enumerate. The book is divided into thirteen sections of diseases of various types with subdivisions. It is encyclopedic in arrangement, accurate, inclusive, terse, and presents all important facts. It is a most handy and reliable volume for study and reference.

HENRY M. MOSES

Refraction of the Human Eye and Methods of Estimating the Refraction. By James Thorington, M.D. Third edition. Octavo of 412 pages, illustrated. Philadelphia, P. Blakiston's Son & Co., 1939. Cloth, \$3.50.

In presenting the third edition of his father's well-known work on refraction, Dr. J. Monroe Thorington has wisely retained much of the original text, which was prepared with such meticulous care many years ago that it is still the standard book on the subject in America.

The treatment of the subject of optics and the description of prisms and lenses and their actions are handled in a way that is clear to the beginner and to those who have difficulty with mathe-

matics. (At the same time the matter is covered so thoroughly that the student is left with a clear conception of the subject.)

Practical refraction with and without cycloplegics, the use of the ophthalmoscope, retinoscope, and other aids are set forth briefly but without any sacrifice of details. The chapters on the action of the extrinsic ocular muscles and their abnormalities, the various phorias and tropias, and methods of treatment leave little to be desired.

Orthoptic training, telescopic, and contact lenses have been included in this edition, so that the work is entirely up to date.

This is an ideal textbook for the student, and it belongs in the library of all who refract.

WALTER V. MOORE

The Essentials of Modern Surgery. Edited by R. M. Handfield-Jones, M.C., and A. E. Porritt, M.A. Quarto of 1,126 pages, illustrated. Baltimore, William Wood & Co., 1938. Cloth, \$9.00.

This textbook of surgery represents the contributions of fifteen English surgeons who have taken part in the presentation of the material included in the book. There are 47 chapters and an index at the end. The chapters cover the whole realm of surgery. The principles of anatomy, physiology, and pathology are stressed. The details of operative treatment are not included. The nature of the treatment, however, is given. Many of the contributors are specialists in the subjects they present. The text is abundantly illustrated with x-ray negatives, photographs of surgical conditions, and drawings. The text and illustrations make the book attractive, and the volume in general is comprehensive but still sufficiently concise for the use of the student and the young graduate in surgery, and for them it is recommended.

EMIL GOETSCH

The Diagnosis and Treatment of Diseases of the Thyroid. By James H. Means, M.D., and Edward P. Richardson, M.D. (Reprinted from Oxford Monographs on Diagnosis and Treatment.) Octavo of 367 pages, illustrated. New York, Oxford University Press, 1938. Cloth, \$5.00.

This book is divided into nine chapters covering Historical Considerations, Functions and Diseases, Principles Underlying the Diagnosis and Treatment, Colloid, Exophthalmic and Adenomatous Goitre, Myxoedema and Cretinism, Malignant Tumors, and Inflammations of the Thyroid. The text is based largely upon the experience of the authors in the medical treatment per se, and the medical therapy associated with the surgical treatment of diseases of the thyroid.

Illustrative cases are appended to almost every chapter. Careful follow-up studies have been done and ultimate results are freely discussed. The book is recommended particularly for the presentation of the medical man's point of view of the care of thyroid patients. However, the surgical treatment does receive adequate presentation. There are many charts to illustrate the text. It would be desirable to have more of the pathology presented, but the book was primarily intended for the presentation of the clinical aspects. The text is readable and

interesting. A comprehensive bibliography is appended to each chapter and there is a full index. The book is recommended particularly for physicians, but should also be valuable to surgeons treating thyroid diseases.

EMIL GOETSCH

Pastoral Psychiatry By John S. Bonnell. Octavo of 237 pages. New York, Harper & Bros., 1938. Cloth, \$2.50.

From time immemorial religion has had a strong influence on human behavior. One need but observe the thousands of people entering and leaving churches on a Sunday morning in any part of any civilized community to realize the potent influence that it exerts on human beings and their conduct. Many a minister has helped his parishioners to pass through emotional crises.

The author of the book under discussion is a minister whose early childhood and adolescent experiences and training have uniquely qualified him as a healer of mental ills. His father was an attendant in a mental hospital and the author spent many a day accompanying his father on his rounds. Moreover, he, too, has served for a short time as an attendant in that institution. A psychotic patient helped him with his studies in preparation for college entrance examinations.

As the author says: "The physician works with the body, the psychiatrist with the mind, and the pastor with the soul. But soul, mind, and body act and react upon each other. The body influences the mind, the mind reacts upon the body, and the health or unhealth of the soul will have a determining influence on both mind and body. Many disorders of the body and mind are due to maladies of the soul with which only a spiritual ministry is equipped to deal."

Many a physician has recognized the minister as an ally in the fight against diseases.

The book is both interesting and instructive. The technique of psychotherapy practiced by the author, as evidenced by the descriptions of typical conversations with parishioners and his methods of dealing with their problems, extends beyond the horizon of medical psychiatry but will win the approval of the intelligent physician and psychiatrist. The book is written in a highly sympathetic tone by an inspired and gifted minister, and should find a wide circulation among intelligent and cultured people.

IRVING J. SANDS

Outline of Psychiatric Case-Study. A Practical Handbook. By Paul W. Preu, M.D. Duodecimo of 140 pages. New York, Paul B. Hoeber, Inc., 1939. Cloth, \$1.85.

Although there are available a number of "outlines," of psychiatric case-study methodology, the present volume under review is by far the most comprehensive. It is essentially formulated by Dr. Preu, but represents the point of view of the Department of Psychiatry and Mental Hygiene of the Yale University School of Medicine, which is under the leadership of Dr. Eugene Kahn.

The content of this handy-sized publication contains only that material that has been tested over a number of years by virtue of practical application at the New Haven Clinic as well as other important centers.

Of particular value will be its usefulness in the training of house officers and psychiatrists-in-training in learning the essentials of the technique of psychiatric history-taking and mental examination. The book is highly recommended.

FREDERICK L. PATRY

A Textbook of Neuro-Radiology By Cecil P. G. Wakeley, F.R.C.S., and Alexander Orley, M.D. Quarto of 336 pages, illustrated. Baltimore, William Wood & Co., 1938. Cloth, \$8.00.

This is an illustrated treatise of 296 pages with an appended bibliography of 29 pages, purporting to include in a single text the present-day knowledge concerning abnormal findings disclosed by roentgen-ray examination in certain diseases of the central nervous system and its coverings. Although the many subjects considered are discussed under separate captions, the facts presented are primarily concerned with information derived from a study of plain roentgen-ray films of the head and spine, and that derived from films taken after the introduction of contrast media into the intracranial and intraspinal spaces (air, lipiodol and thorotrast). Methods of technique are described. The textbook should be of considerable value to those practicing general radiology.

E. JEFFERSON BROWDER

Angina Pectoris. Nerve Pathways, Physiology, Symptomatology, and Treatment. By Heyman R. Miller, M.D. Octavo of 275 pages, illustrated. Baltimore, The Williams & Wilkins Co., 1939. Cloth, \$3.25.

In this well-printed volume the author essays a restatement and analysis of the character of angina pectoris. He presents a graphic delineation of the pathways of cardiac pain, with 38 illustrative drawings in collaboration with L. Lyons Vosburgh.

Decrying the use of the terms "false angina" and "pseudoangina," he quotes Potain (1880) to the effect that "there are no false diseases, but there are only false diagnoses."

It is not apparent at first that coronary occlusion is included in his survey, but we find that all pain from coronary mishap to psychoneurosis is grouped for consideration under his title. He considers angina pectoris as an "effect of mass action of the whole autonomic system" "a paroxysmal upheaval," sympathetic and vagal.

The book is an interesting one. Clinical comments are well presented. That the severity of cardiac pain is not a measure of pathologic changes is stressed, and there is a splendid review of the simulation of anginal pain by non-cardiac diseases.

The views of Head and Mackenzie in regard to the viscerosensory reflex are questioned and criticized.

Seventy pages are devoted to treatment, medical and surgical, of the anginal syndrome, organic and otherwise. Details are given with critical comments. The text is naturally a few months behind the later work of Claude Beck and the work of O'Shaughnessy of London.

The bibliographies are a delight and one easily finds therein the references often sought when memory fails and memoranda are mislaid.

FRANK B. CROSS

You and Heredity By Amram Scheinfeld assisted in the genetic sections by Dr Morton D Schweitzer Octavo of 434 pages, illustrated New York, Frederick A Stokes Co, 1939 Cloth, \$3 75

This book is written from the viewpoint of a reporter who obtained information concerning the general field from those working in it

The style of the author is extremely interesting Each chapter presents specific subject matter profusely illustrated with drawings Such topics as the division of the chromosomes, the determination of sex, and specific traits such as the color of the eyes and hair, are presented Particularly interesting to the reviewer was a discussion on musical talent which was an original genetic study carried out by the author Also of interest were the summary tables of what the author calls "black genes" In these there is an attempt to forecast the chances of transmission of any given defect, disease or abnormality, to a child The disease processes such as rheumatism, diabetes, eye pathology, ear abnormalities, skeletal defects, etc, are presented in detail with the possibilities of their transmission Finally, there is a discussion of race, ancestry, and eugenics with a program for the future

The book contains in its appendix a chart of the high lights in the history of genetics and a very good bibliography for further reading on the subject The reviewer commends this book highly, and feels that it will be interesting reading for any member of the profession

STANLEY S LAMM

Handbook of the Vaccine Treatment of Chronic Rheumatic Diseases By H Warren Crowe, M.R.C.S Third edition Octavo of 95 pages New York, Oxford University Press, 1939 Paper, \$1 25

This small book is a concise, practical, and clear exposition of vaccine treatment of chronic rheumatic diseases as practiced under the direction of Dr Crowe While a number of the premises expressed may be at variance with those presently in common vogue, it behooves every practitioner delving into the vaccine treatment of "chronic arthritis" to be cognizant of this monumental little treatise The reviewer specifies "chronic arthritis," for in his opinion this group of diseases constitutes a unique immunologic entity, with implications from the treatment viewpoint which are not duplicated in other diseases treated by vaccine.

Dr Crowe's success with vaccine treatment hinges on the meticulous care with which dosage is regulated, the scrupulous avoidance of reactions and adherence to the principle of small dosage and clinging to the "optimal dose" for the individual The administration of ten thousand or one thousand organisms approaches the mythical in the eyes of those who start with five or ten or one hundred million, it nevertheless seems to be borne out by statistics that most authorities claiming failure with vaccine therapy are to be listed among the exponents of large dosage Whether one uses vaccines, filtrates, or other bacterial products in this group of diseases, and whether or not one feels that the *modus operandi* is as expounded, the principles put forth by Crowe are the *sine qua non* of success with any bacterin treatment.

GEORGE E ANDERSON

The New International Clinics. Original Contributions Clinics, and Evaluated Reviews of Current Advances in the Medical Arts. Edited by George M Piersol, M D Volume IV, New Series One Octavo of 349 pages, illustrated Philadelphia, J B Lippincott Co, 1938 Cloth, \$3 00

Many important phases of medicine and surgery are covered in this number of the International Clinics Jolliffe, of Bellevue, reviews the more significant features of vitamin B₁₂, as applied to the American diet. There is a comprehensive study of all the various types of hypertension by Held and Goldbloom Kalt reider, of Rochester, New York, presents an excellent summary of the difficulties frequently encountered in attempting to differentiate between pulmonary and cardiac insufficiency in chronic pulmonary disease He emphasizes the importance of laboratory aids The volume includes several interesting pages on endocrine problems, functional colonic disorders, and prolapse of the rectum

ANDREW M BABEY

Manual of Roentgenological Technique By L R Sante, M D Sixth edition Octavo of 253 pages, illustrated Ann Arbor, Edwards Bros, Inc, 1939 Cloth, \$4 50

This book is another excellent example of a most useful type of reference and textbook printed by the photo-lithographic method This method of printing and reproduction of photographs is just as satisfactory as other more commonly used methods, and has the very distinct advantage of reducing the cost far below that which would be necessary by any other method

The subject matter, arranged in a simple manner, is complete and well classified for easy reference With all its simplicity there is a wealth of essential detail which makes this an outstanding work in its field

A L L BELL

End-Results in the Treatment of Gastric Cancer An Analytic Study and Statistical Survey of Sixty Years of Surgical Treatment. By Edward M Livingston, M D, and George T Pack, M D Quarto of 179 pages, illustrated New York, Paul B Hoeber, Inc, 1939 Cloth, \$3 00

This text is a statistical study of gastric cancer over a period of sixty years The stomach occupies a most important position from the standpoint of initial cancer The figures should be both important and instructive. Needless to say they have discovered a much higher incidence of operable carcinoma than has been reported on the side of the chart which is concerned with the operative cases In other words, the conclusion reached is that there are thousands of patients who are being denied the benefits of surgery In their analysis this is capable of correction Team work and a more careful study of gastric cases would increase the number of successful operative cases

This monograph is not fatiguing because of statistics The lesson learned from the statistics has been mentioned For both the student and the teacher it should prove an important reference on gastric cancer

Untimely and Undesirable

The American Association for Social Security will make a strong effort to force its compulsory health insurance bill through the current session of the New York State Legislature. Apparently the advocates of this system fear that if voluntary medical expense indemnity insurance succeeds, their scheme is doomed. They would like to rush their program through before voluntary insurance has had a chance to prove its worth.

The present moment is singularly inopportune for the adoption of a controversial measure like compulsory sickness insurance. For one thing, as stated above, the country has embarked on its first important trial of voluntary insurance. If the voluntary insurance works, it would provide all of the alleged benefits of compulsory insurance without its disadvantages. It is obviously the part of common sense to give noncontroversial voluntary methods a chance before resorting to compulsion. Falling morbidity and mortality rates show that there is no emergency to justify sabotaging the experiment in voluntary insurance in favor of a compulsory contributory system.

Apart from the comparative merits of compulsory and voluntary insurance, however, there are strong reasons for rejecting the bill proposed by the American Association for Social Security. Governmental economy is essential to the preservation of the American system. The government cannot evade its obligation to provide adequate medical service to the indigent. There is no necessity for it to undertake the financial burden of compulsory sickness insurance in behalf of the middle class, when voluntary plans are being adopted all over the country to supply the needs of this very group.

Not the least among the arguments against compulsory sickness insurance is its threat to personal independence. The vast political

bureaucracy, which experience has shown to be an inevitable concomitant of obligatory sickness insurance, is an instrument of pressure against the layman as well as the medical profession. New York and every other state should think twice before loading its citizens with oppressive new taxation and bureaucratic controls for a scheme that has nowhere fulfilled the promises held out for it.

Wise Distribution

The policy enunciated by the New York State Association of School Physicians preserves an equitable balance between the school doctor, the health officer, and the private practitioner. The interests and duties of each are wisely defined and prescribed.

School health services aim to create a wholesome sanitary environment, to disseminate authentic health information, to build up sound health practices, and to provide first aid to teachers and pupils in accidents and emergencies. The school physician should see that every child has a thorough annual examination and that defects found are corrected; he should issue regulations governing light, heat, ventilation, and cleanliness and take all necessary steps to prevent the spread of communicable disease. Essentially, however, his role is executive and educational; the school should not maintain clinics nor provide treatment.

On the private practitioner falls the duty of performing the annual medical examination, correcting any defects discovered and providing immunization. The family doctor's knowledge of his patients is an invaluable asset in the performance of the health examinations, provided, of course, that this knowledge is not made an excuse for casual inspection and certification. The examination should be painstaking and complete and follow the course laid out by the Department of Education.

Should the family doctor fail to provide immunization, the Health Department may rightfully step in. Likewise, the school physician may take the initiative to secure the correction of remediable defects neglected by the private practitioner.

Under this policy, the function of these three servants of child health supplement one another but do not overlap. The family physician is primarily responsible for performance of the health examination but the school physician prescribes its form and fits its results into the general school health program. Both the school physician and the public health officer are concerned with the prevention of communicable diseases but they need not duplicate each other's efforts. While the Health Department and the private practitioner are both charged with responsibility for immunization, the usual arrangement is for the Health Department to supply the

materials while the family doctor performs the treatment. This is an example of effective cooperation growing out of sound judgment and good will.

The Student Section

All physicians concerned with undergraduate medical teaching, postgraduate medical instruction, and hospitals wherein interns and residents are trained should acquaint themselves with that portion of the *Journal of the American Medical Association* called the "Student Section." Herein are contained articles devoted to the educational interests of students, interns, and residents. The latter should be made aware of this portion of the *Journal* and of the role that it plays in the general education of a physician.

There are factors other than scientific knowledge that are necessary for the delivery of a perfect physician. During student days they are scarcely considered because the emphasis has to be placed upon the fundamentals of medicine. During internship, as well as residency, the budding practitioner has little time to devote to anything besides learning how to apply in practice what he has learned at medical school. If these other factors—community interests and obligations, the love of the arts, the development of a social consciousness, and the need for free and frequent interchange of thoughts in fields sometimes far distant from medicine—are not emphasized during the formative stage of a doctor, they may be so vastly overshadowed by the stress placed upon pure medicine that their importance may never again be clearly seen through the dense fog of a one-sided professional training.

The "Student Section" is meeting this need, improvements in the service it renders will be made as time goes on. We suggest, humbly, that some improvements should be made shortly—a book-of-the-month (nonmedical, of course), recommended reading of current medical literature for interns and residents in the specialties, comparisons of the varied systems of medical practice existent throughout the world, and many, many others. To return to our original thought, however, we again call the attention of all interested in the training of a physician to this important section of the *Journal of the American Medical Association*.

Chronicity and Vitamin C

The significance of vitamin C deficiency in the prolongation of an acute infectious process and its continuance into the stage of chronicity has been discussed in the recent literature. From the

various reports at hand, C-hypovitaminosis unquestionably is a factor which, while as yet not fully determinable as to its influence in these cases, is a definite concomitant of malnutrition in children. Bernfeld, *et al*,¹ studied one phase of this problem in cases of purulent otitis media in children which did not yield readily to local treatment. In 53 children, wherein a chronic purulent otitis, presenting a central perforation through the drum, persisted for more than a year, they found a poor resistance to upper respiratory infections in approximately one-third of the cases under their surveillance. Malnutrition, underweight, and cervical adenopathy were noted in 50 per cent of these children. What seemed to them significant was that a deficiency in vitamin C was apparent in more than 50 per cent of their cases.

This report has been selected merely to stimulate discussion of one problem in chronic infections. There is no issue with the findings of these observers. But, when it concerns the elements involved in the production of a chronic purulent otorrhea, one cannot discard the basic studies of Wittmaack and Eckert-Mobius among others which have proved that developmental and anatomic factors vitally affect the course of an otitic suppuration. Perhaps the histologic findings of these men may give way to observations such as recorded by Bernfeld but further proof is wanted. Until it is forthcoming, the conception of chronic otorrhea as first clearly elucidated by Wittmaack will still stand unquestioned. In brief, this is that any interference with the normal process of pneumatization of the temporal bone will cause such histoanatomic variations which lend themselves readily to a chronicity in the face of an otitic infection.

¹ Bernfeld, *et al*. Ann. Pediat. 153: 222 (1939)

Current Comment

"The American people should not be willing to discard a medical system that has made them the healthiest nation in the history of man"—Lowell Lawrence, of Kansas City—a layman who writes on the economic aspects of medical care in the October issue of *Hygeia*

"It is said the average American family pays the doctor seventy-five dollars a year. This will be real news to the doctor"—A recent comment in the *Norfolk Ledger-Dispatch*

"We may yet hope to see the day when the great educational power of radio will become the handmaiden of medicine in its tremendous task of sound health education"—L. D. R., in the *St. Louis County Medical Society Bulletin* of December 22, 1939

"A healthy man must feel unhappy when he listens to the medical ballyhoo on the radio and realizes how easily, surely, and pleasantly he could be cured of many interesting ailments, if he only

had them"—The immediate situation, commented upon by the *Milwaukee Medical Times*

. . .

"Every organization has, roughly, two components, those who do and those who don't. It isn't the former to whom these remarks are directed. Right or wrong, he is in there giving of his best, not infrequently damned by the faint praise of the inertia of the don'ts

"The future of medical practice is in the hands of the medical profession of today. Your responsiveness to and the handling of the changing conditions will determine whether medicine is to be a leading and constructive force in a changing society. You cannot ignore the situation. If you don't make it right someone else will. So get out to meetings, get on committees, acquaint yourselves with the problems to be solved and give of your time and thought. You are the best educated of any group in the community of which you are a part. Why not put that education to work for yourself and the community?"—H. E. Patrick, M.D., in the December issue of the *Bulletin* of the Mahoning County Medical Society of Ohio

. . .

"Those of you who think the Wagner Medical Practice Act is a dead issue are living in a fool's paradise. Wait until the next session of Congress. And if by kind providence the blow should not fall then, read what was said in a recent address by Senator Robert A. Taft. 'I believe that in 1940 a Federal Medical Program of some kind will be adopted. What form it takes depends largely on the medical profession—I believe a Federal aid program can be worked out—I believe it can be worked out with the assistance and cooperation of the doctors themselves'

"The last sounds a little encouraging and takes away some of the sting. But remember, there are doctors and doctors. There are doctors in medical schools who are better teachers than they are practitioners. There are doctors who are better

politicians than practitioners. There are doctors who are purely public health men. There are doctors who represent the A.M.A. Which ones will be consulted? It makes a great difference where the co-operation comes from, even in the medical profession"—Some paragraphs from "The Medical Crier" in the September, 1939, issue of the *Bulletin* of the Mahoning (Ohio) County Medical Society

. . .

"It is the American way of practice that has made us the most healthful nation in the world. Improvements are necessary and the medical profession is constantly improving the distribution of its services as well as its curative and preventive practices. The European way of practicing medicine has been a big influence in the upbuilding of dictatorships, centralization of governments, and wars. Why should we change from our American way?"—We quote from the *St. Louis County Medical Society Bulletin* of recent date

. . .

"Medical education has always been individualistic from ancient preceptorial teaching down through the modern schools. The single variant is the matter of public health, a comparatively recent field of postgraduate specialization. Other than this, the hospital clinics—originally but now secondarily a teaching function of medicine—are the nearest approach to mass medicine of which the profession has had any experience. It is unfortunate surely, and possibly tragic, that the philosophy and practice of medical education are so little known, so badly understood outside of the profession itself. Because, even if it were possibly, a profound revision of medical education and almost complete reversal of its ethics would be necessary if the profession were to be industrialized"—The *Westchester Medical Bulletin* for November

.

"It is as vital to our ultimate success and happiness to keep the controlling hand

of the self-seeking politician out of our hospital system as it is to keep it out of our school system"—Ray Lyman Wilbur, M. D.

. . .

"Democracy was no miraculous improvisation, no full-grown energy, but a growth and development. Overnight perfectionists please observe and preserve."—A reminder and a suggestion from the *New York Times* of December 7, 1939

"Medicine has problems—and with the understanding, sympathetic aid of people in all walks of life, these problems are being solved with a resultant gain in life-expectancy so great as to create of itself still more problems to be solved. But medicine appreciates from long laboratory experience that change does not necessarily mean progress, and organization is not synonymous with efficiency.

"The health achievements of our nation, with its mixed national strains, have not been made in spite of—but because of—our failure to adopt foreign procedures. Our gains have been made because we had the foresight to avoid the basic concept of 'care only within limits.' A medical profession shackled to systematized control under the claim that thus will economic security be advanced will result in patients who must abide by rules and doctors who find themselves unable to do that which their training indicates as essential for the sick. Is this not too great a purchase price to pay?"—From an address by Mr. J. G. Crownhart at the annual meeting of the Medical Society of Westchester County on November 21, 1939.

.

"There is an analogy between the practice of medicine and world conditions in general. In every country, including our own, there are those who offer political and economic panaceas. However attractive they may seem, they are unproved theories. Indeed, some nations have succumbed to shrill pipers and

crackpot theorists, who have thrown overboard tried and established methods and are staking everything on doubtful ideological nostrums.

"The result—we are living in a very sick world. So sick that a few more doses of the new remedies may destroy our entire civilization.

"Let us hope that the doctors in charge of the destinies of nations will come to their senses before it is too late. Perhaps it would be even better if the patient himself, the people, were to discover that beneath the sugar coating of the new pills there is poison, and fire the crackbrained doctors. For sooner or later, they must realize that we cannot discard our accepted and tried though not infallible remedies, for new fangled and unproved panaceas. Or is it too much to hope for?"—L. S. D., writing on "Panaceas" in the November issue of the *Bulletin* of the Mahoning (Ohio) County Medical Society.

"We believe organized medicine can do a better job than the government and by a better job we mean deliver a much higher quality of medical service to the American public. Let us all cooperate to show the public that we can deliver the goods and on a quality basis."—We most certainly are in accord with these sentiments, expressed in the Oakland County (Michigan) *Medical Bulletin* a short time ago.

. . .

"If government provides the indigent with food and clothing, why the failure to provide medical care, when the profession is fully cooperative in this respect? If government has not yet succeeded in the simplest part of the problem, comprising the indigent, is it safe to give it control of the greater and more complicated part, that of medical care for the employed and self-supporting?"—Pertinent remarks of Terry M. Townsend, president of the Medical Society of the State of New York.

Sulfapyridine Urolithiasis

MORRIS ROBERT KEEN, M D , Huntington, New York

THE rapidly changing panorama of effective medication within the past few years has been accompanied by precarious and dangerous sequelae. Sulfapyridine (a para-amino-benzene sulfonamido-pyridine) with its dramatic results in certain pneumonic processes comes within this group of erratic drugs. For a pneumonia patient to recover overnight, as it were, and then to be precipitated into an acute abdominal syndrome is an unpleasant aftermath for the patient as well as his physician.

The urinary complications following the use of this drug have recently been brought to light from several angles. From the experimental phase, two groups of observers have presented evidence of a most interesting nature. Antopol and Robinson,¹ working on rats, rabbits, and monkeys, noted the formation of urinary concretions, even after a single large dose of sulfapyridine. With repeated feedings, the production of uroliths was more pronounced. Certain species, such as mice and dogs, were not susceptible to stone formation even on large doses of sulfapyridine. Clusters of crystals were found as early as twenty-four hours after the onset of the medication. These "aggregates of crystals" predominated in the lower ureter at the level of the bony pelvic brim. However, the renal pelvis was, at times, distended with blood and crystals. The pathologic picture produced within the kidney varied with the degree of urinary stasis. First seen was a calculus ureteritis followed by pyelitis and a pyelonephritis. A finding of clinical significance is the definite thickening of the ureters and the renal pelvis without associated calculi, present two and a half months after the discontinuance of the medication.

The striking and thorough experimental data of Gross, Cooper, and Lewis² so clearly simulates the clinical picture

as to warrant repetition and emphasis. Noting that their animals, although freed of pneumonic infections, succumbed, these workers proceeded with detailed protocol studies. More than 60 per cent of their animals (27 of 39) on a daily diet of 1 Gm of sulfapyridine per kilo of body weight developed calculi within two weeks. These calculi localized at almost any level of the urinary tract. Obstruction was either complete or partial and was accompanied by hematuria, pyelonephritis, and an elevated blood nitrogen. Death appeared secondary to varying degrees of renal damage directly related to the degree of urinary obstruction. The gross pathologic features were enlarged, soft, fluctuant kidneys with dilated ureters and contracted bladders. On section, the renal tissue was swollen, pale, and bulging, with a poorly demarcated cortex. The microscopic features were albuminous degenerations of the tubular epithelium, areas of necrosis, and, in some instances, extensive exudative pyelonephritis. The renal pelvis and ureters, grossly dilated in many cases, presented a smooth glistening mucosa with occasional areas of interstitial hemorrhage. When obstruction occurred at higher levels, the bladders were contracted. No vesical hemorrhage was observed.

In a more recent study,³ Gross and his associates attempted to determine the ultimate fate of the renal ureteral lesions as well as the concretions formed. They concluded that ureteral and pelvic dilations subsided after the discontinuance of the drug (four weeks). This finding is at variance with the definite persistent thickening of the ureter and pelvic walls noted by others. The lesions frequently observed in the kidney were hyaline thickening of the basement membrane of the adjacent convoluted tubules and vesicular engorgement of the nuclei with

FIG 1 CASE J D Arrow mark points to filling defect noted in the pyelogram, and attributed to nonopaque calculus. Another filling can be seen in the inferior limb of the pelvis

karolysis. The glomeruli were essentially normal.

While the calculi may disappear in man as in the experimental animal, their "solution may be impeded by the precipitation of calcium salts upon the surface, as suggested by Antopol and Robinson, or of protein material." Thus, calculi of acetylsulfapyridine origin may actually grow by adhesion or inclusion of the above elements.

The sulfapyridine calculi varied from a grayish white to a pale yellow in color, had a smooth or spiculed surface, and consisted of crystalline needles and plates.

The clinical duplication of the above experiments is seen in the case reports of Southworth and Cooke.⁴ Three patients exhibited hematuria and abdominal pain. An elevation of the blood nitrogen was present in 2 of these. Recovery occurred in all, although the eventual urologic complications remain to be seen.

Hansen's case of a 19-year-old male developed hematuria on the fifth day of medication. The hematuria disappeared in a few days, although the drug was continued. Adalja⁵ reports another case of hematuria that disappeared with the cessation of the drug. In a series of 50 cases, Graham and his colleagues⁶ found 4 patients exhibiting ureteral pain and hematuria. Many jagged crystals were seen in the freshly voided urine. No

urologic studies were undertaken. Perhaps the acuteness of the prevailing illness made such examinations undesirable.

Toomey found jagged crystals in the urine of patients using this drug. Experimentally, he and associates duplicated the pathologic findings of Gross, Antopol, etc.

In treating 27 cases of pneumonia in children, Fulton and his colleagues noted hematuria in 5 cases (18.5 per cent).

Case Reports

The following 2 cases are presented because of their related interest to this subject.

FIG 2 CASE G M Arrow marks point to right renal pelvis, which shows numerous mottled areas due to the mixture of blood and Hippuran dye.

Case 1—J D, aged 52, male, was admitted to the Huntington Hospital on April 3, 1939, because of lower abdominal pain of one day's duration. Ten days previously he had contracted a respiratory infection, accompanied by general malaise, anorexia, fever, and chilly sensations. This was diagnosed as a bronchopneumonia. He was treated with sulfapyridine (total dosage 24 Gm). The day of admission, he developed severe cramplike pain in the right lower groin followed by vomiting. Inability to void or to defecate was present. No previous history of urinary difficulty could be elicited.

Physical examination revealed an acutely ill, apathetic individual. Temperature and respiration were normal. Pulse was 60 per minute. The pupils reacted normally to light and accommodation. The nasal mucosa was congested.

FIG 3 Photomicrograph of crystals (sulfapyridine) isolated from Case J D, magnified 50 times

Fauces were reddened. The pulmonic and cardiac areas were normal to auscultation and percussion.

Abdomen spastic right side with a localized tenderness in both upper and lower quadrants and in the flank. No palpable masses.

The external genitalia were normal to palpation. Rectal examination anal tone good, prostate soft. Both seminal vesicles were boggy.

The extremities were normal in appearance and reaction.

Laboratory Data (April 3, 1939) Urine (catheterized) reaction acid, sp gr 1.021, sugar negative, alb 1 plus, acetone 2 plus, diacetic ac. negative. Micr 1-2 w b c. per h p f, 40-50 r b c, rare clump of w b c. Blood count hemoglobin (100 per cent) r b c. 4,710,000, w b c 11,550. Differential 9 per cent small lymphocytes, 90 per cent polymorphonuclear. Schilling Index juvenile 3, stab 22, segmented 65. Wassermann negative.

Urologic consultation was requested. The features of this examination were rigidity and spasticity in the right lower quadrant, with vague right lumbar distress. An acute surgical abdomen was also considered but final opinion was deferred until a cystoscopy could be performed.

The urologic survey was as follows:

a Plain K U B film. The left kidney is normal in size, contour, and position. The right kidney is obscured. In the right lower part of the abdomen there is a collection of gas in what appears to be a tremendously dilated loop of bowel. There is no evidence of an opaque calculus.

FIG 4 Crystals magnified 70 times

b Cystoscopy disclosed a small, yellowish, ovoid body, $\frac{1}{8}$ " in diameter, protruding from the right ureteral orifice. On the floor of the bladder were several clusters of soft crystalline matter. The bladder neck showed some elevation in the midline. Intravenous indigo carmine appeared within five minutes from the left ureteral orifice and none from the right side after fifteen minutes. With a ureteral catheter, the yellowish ovoid body was dislodged from the ureteral orifice and a catheter then passed to the right renal pelvis without any difficulty. A strong blue was obtained from the right renal pelvis. Catheterization of the left ureter was uneventful. The rate of flow from the right side was twice that of the left. Divided urines were as follows:

Specimen	Micros	Gram Stain	Culture
Right kidney	0-5 w b c	No organism	Sterile
Left kidney	15-20 r b c 1-4 granular casts 1-10 hyaline casts		
Bladder	10-15 r b c Shreds 20-25 r b c 1-2 w b c		

Bilateral pyeloureterograms were performed with 20 per cent sodium Hippuran. A No 5 F ureteral catheter was left within the right renal pelvis.

c Pyelographic report. Left renal pelvis calyces, and ureter appear normal, right renal pelvis and calyces are somewhat dilated, a circular filling defect is noted in the upper major calyx.

A tentative diagnosis was made of right renal obstruction secondary to ureteral calculi, possibly of sulfapyridine origin. This diagnosis was facilitated by a previous conversation between our resident, Dr W Bennett, and Dr Lawrence of the New York Hospital. The latter had ob-

	Microscopic	Gram Stain	Tbc	Culture
Right	Hyaline casts, many r b c	Negative	Negative	Sterile
Left	R b c. 3-4	Rare gram neg cocci	Negative	Staphylococci
Bladder	R b c. 1	Negative	Negative	Staphylococci
All specimens contained a brownish debris				

served this renal phenomenon in pneumonia patients treated with sulfapyridine

Analysis of crystals isolated from ureter and bladder a small portion of the urinary calculus was dissolved in dilute hydrochloric acid To the resulting solution, a small amount of sodium nitrite was added The mixture was then chilled To this solution, an equal amount of alpha dimethylnaphthylamine was added and allowed to stand at room temperature A deep red color resulted This was chemical evidence of the presence of a nitrated benzene ring—W R Powers, M D

Clinical Course April 5, 1939 catheter drainage removed, no complaints, T P R normal April 7 slight attack of right renal colic, fluid output copious April 9 patient is up and about, voids without difficulty April 12 discharged Urine showed a trace of albumin, 8-10 w b c, 1-3 r b c, and few clusters of w b c.

Case 2—G M, aged 29, was admitted to the hospital on April 13, 1939, because of severe pain in the right loin, radiating to the groin, associated with painful urination Five days previous, he had experienced chills, a cough, and left posterior chest pain Fever was 101 F, pulse 120, blood pressure 125/80 At the time, coarse rales were heard at the left base posteriorly, but no dullness A diagnosis of pneumonia was made and confirmed by a medical consultant Sulfapyridine was started with a dose of 2 Gm Total dosage was 9½ Gm Nausea, abdominal cramps, and diarrhea developed The temperature and pulmonary signs abated within forty-eight hours after beginning the drug

The past history was essentially negative save for an occasional period of urinary frequency Physical examination revealed an extremely apprehensive male. Temperature, pulse, and respiration were normal The pupils were dilated but reacted well to light and accommodation The nasal mucosa was congested Fauces were clear The pulmonic fields were normal save for some dullness with a few crackling rales at the right base posteriorly The cardiac field was normal Blood pressure was 120/85 Abdomen definite rigidity and tenderness in the right lower quadrant and the right costo-vertebral angle Genitalia penis and scrotal contents were normal to palpation. Rectal anal tone good Prostate soft and small Ex-

trémities normal in appearance, reflexes normal

Laboratory Data (April 14, 1939) urine color straw, clear, reaction acid, sp gr 1.022, alb faint trace, sug negative, acetone negative, micr 1 w b c. per h p f Blood count hemoglobin (79 per cent), r b c 4,600,000, w b c. 10,600, polymorphonuclear 78 per cent Small lymphocytes 4 per cent, large monocytes 6, large lymphocytes 12 per cent. Wassermann was negative.

X-ray examination of the chest showed a slight increase in the bronchial markings in both lower lobes The appearance was that of a bronchitis The diaphragm moved freely on both sides and the heart was not enlarged

Urologic survey was as follows

(a) Plain x-ray of the urinary tract showed both kidneys to be normal in size, contour, and position and there was no evidence of an opaque urinary calculus

(b) Cystoscopy revealed a reddened and edematous mucosa in the region of the right ureteral orifice Intravenous indigo carmine appeared promptly from the left ureteral orifice. None was seen from the right side in fifteen minutes At the end of this period a ureteral catheter was passed to the left renal pelvis without encountering any obstruction Return flow was of normal rate and grossly clear The right renal pelvis, when catheterized, drained old sanguinous fluid profusely for about ten minutes Divided kidney studies were as listed in above table

When the right ureteral catheter was withdrawn, a stringy clot was seen protruding from the ureteral orifice This clot, when examined under the cystoscopic lens, contained several tiny, yellow, ovoid bodies

(c) Right pyeloureterogram disclosed some dilatation of the renal pelvis and calyces The density of the right renal pelvis was less than normal as though the solution were mixed with a nonopaque substance such as air or blood

Diagnosis right renal obstruction secondary to old blood clots, renal irritation possibly secondary to crystals of sulfapyridine. Tumor of the renal pelvis to be excluded

Advise indwelling right ureteral catheterization and pelvic lavage

Clinical Course (April 14) right ureteral

catheter not draining No improvement following irrigation, removal of the catheter (April 15) no renal tenderness Fluid forced, some elevation of temperature (April 16) acute right renal pain, dysuria, and nausea. Two small blood clots passed Temperature, pulse, and respiration normal (April 18) out of bed No renal tenderness (April 19) recurrence of severe right renal pain. Tenderness present in the right costovertebral angle Right abdominal muscle spasm is present Urine shows a trace of albumin, 10-15 w b c and 2-4 r b c. (April 20) Sudden relief of pain Temperature 99 F Discharged for further observation at the office (May 19) one attack of right renal distress which subsided spontaneously Intravenous pyelography shows a normal left pyelogram but an incomplete filling of the right renal pelvis There is a suggestion of a small filling defect within the pelvis

Both cases developed acute renal obstruction following the ingestion of sulfapyridine in amounts varying from 9 to 24 Gm Crystals simulating sulfapyridine were found Red blood cells and casts were present in the urine from the affected kidneys One case subsided spontaneously following catheter drainage and increased fluid intake. The other has had several recurrent attacks of right lumbar pain A recheck intravenous pyelography showed a small defect in the right renal pelvis (residual clot³) At no time did the urinary output diminish to an alarming degree. Unfortunately, blood nitrogen studies were not done A moderate leukocytosis with a polymorphonuclear increase was noted Temperature reaction was slight. An acute surgical abdominal condition seemed possible at one time

The factors in the production of sulfapyridine calculi may be

- 1 The marked dehydration of a toxic pneumonia patient.

- 2 The proved limited solubility of

sulfapyridine (1 1,000) room temperature and the even greater insolubility of the acetylated derivatives (Cooper, Gross, and Lewis)

Conclusion

- 1 Two cases of right renal obstruction secondary to sulfapyridine therapy are presented

- 2 The experimental background emphasizing the clinical picture is reviewed

- 3 The possibilities of future urologic complications (nucleus of permanent stone formation and ureteral wall damage) are stressed

Since this article was submitted for publication (June, 1939), Snapper and his associates reported the occurrence of hematuria and colic during sulfapyridine treatment both in children and adults A renal calculus composed of acetylsulfapyridine crystals was found in one adult

Plummer and Emsworth have recently stated that the drug's toxic effects involving the kidneys and ureters were the most disturbing Two adults of their series developed definite renal calculi

INTERNATIONAL COLLEGE OF SURGEONS

The officers of the United States Chapter of the International College of Surgeons cordially invite all physicians and surgeons in good standing to their Fourth Assembly, to be held in Venice, Florida, February 11-14, 1940 There is no registration fee

For general information address Dr. Fred H. Albee, chairman, 57 West 57th Street, New York City For information about the presentation of scientific papers or exhibits, query Dr. Charles H. Arnold, secretary of the Scientific Assembly Terminal Building, Lincoln, Nebraska

STUDIES IN THE GROWTH AND DEVELOPMENT OF CHILDREN

HARRY BAKWIN, M D , and RUTH MORRIS BAKWIN, M D , New York City

(From the Department of Pediatrics, New York University, and from the New York Infirmary for Women and Children)

WITHIN recent years there has been an increasing interest in the problems of growth and development. I propose to discuss today two applications from these studies to the practice of pediatrics: first, the use of standards of physical growth, and second, the significance of a knowledge of growth and development for the psychologic care of the child.

Standards for Physical Growth

The standard that is at present most widely used is the Baldwin-Wood table. It is represented as an age-height-weight table, but a moment's study will show that it is actually a height-weight table and that age might have been omitted without causing any very serious error. It is assumed, according to the Baldwin-Wood table, that if the child's weight for his height corresponds to that on the chart, the child is normal. The assumption here is that height is a sort of fixed point and is not influenced by, let us say, an inadequate diet. But this is not true. Height is influenced by the environment in just the same way as is weight. (We cannot say which is more influenced, since inches and pounds cannot be compared.)

The Baldwin-Wood table is the simplest of the available standards. There are others that include more measurements. Thus Lucas and Prior include hip breadth in their growth standards. But the diameter of the hips happens to be one of the measurements that is influenced by an adverse environment even more than is height.

There are some standards which make necessary a great many more measurements for an estimate of proper weight.

Of course, it is apparent that if enough body measurements are taken, such as height, size of extremities, thickness of subcutaneous fat, etc., it will be unnecessary to weigh the child in order to make a prediction of weight. Whether this serves any useful clinical purpose is highly doubtful.

The requirements for proper growth standards are

- 1 They should be based on children who receive most nearly optimal care. Standards obtained from children who are themselves improperly cared for and hence below par are of little value. The standards which we have prepared are based on the weights and heights of private school children in New York City. It is probable that this group has received as good medical supervision as is available.

- 2 Separate standards are necessary for boys and girls. This may seem obvious but, curiously enough, the curve most widely used for infants does not take sex into consideration, although boys weigh about 10 per cent more than girls during the first year of life.

- 3 Separate standards are necessary for colored children. They grow more slowly than white children, and though this may be due to poorer hygienic surroundings, it is hardly justifiable to make this assumption without more data.

- 4 Standards should be simple. We believe the most suitable standard at the present time is the age-weight and age-height standard.

- 5 Proper standards should indicate, in addition to the average growth curve, some measure to show how children vary around the average. We have used for

Read at the Annual Meeting of the Medical Society of the State of New York, Syracuse, New York, April 26 1939

this purpose a statistical device called the standard deviation. If we construct charts or tables which take into account the standard deviation we obtain a zone around the average which includes two-thirds of normal children. One-sixth of normal children will be above this and the remaining one-sixth below it (see Fig 1).

It is hardly necessary to state that growth standards in no sense replace clinical judgment. They can, however, be useful as aids if they are properly used. Generally speaking, it is fair to state that the farther away a child is from the average for his age, the more likely he is to be abnormal. Furthermore, when repeated measurements are made on the same child, growth standards may be very valuable in that they show whether the child's growth is keeping up with or surpassing his group.

Psychologic Growth and Development

It is becoming increasingly apparent that the child must be looked upon as an integrated unit and that optimal child care should include psychologic as well as physical care. Proper psychologic care, like proper physical care, requires an understanding of the principles underlying growth and development. We need to know to what extent the child can be expected to adapt to the environment and to what extent the environment must be adjusted to the child.

The child's adaptability is limited by his developmental plan. It is now pretty generally accepted by students of this subject that development or maturation takes place according to a plan and a sequence that is innately determined and that cannot be readily altered by attempts at acceleration or retardation. The child's psychologic traits—his motor skills—his ability to acquire information, his emotional responsiveness—emerge according to a plan and a sequence that differs for each individual child. The developmental pace is set by the germ plasm. It is for us to see to it that an environment is provided which will give the child optimum opportunity for

FIG 1 Weight curve of girls from birth to 14 years. The continuous line represents the average weight. The clear zone on either side of this line includes approximately two-thirds of normal girls and each of the shaded zones the remaining one-sixth. For example, if one were to weigh 100 healthy girls, one would expect to find approximately 16 in the upper shaded zone, 33 in the clear zone above the continuous line, 33 in the clear zone below the continuous line, and 16 in the lower shaded zone. About 2 per cent would fall outside the shaded zones.

growth within the framework of the developmental stage at which the child happens to be.

I should like to call your attention at this point to the difference in the concepts of development and growth. The term "development" refers to the unfolding of the mature pattern. It refers to the innumerable stages and processes through which human form and function pass from birth to maturity. Growth, on the other hand, is strictly a quantitative concept and refers to change in size or to increase in information, skills, or emotional interests.

The emergence of the psychologic developmental plan, like the physical, is obligatory and not optional. The child must be permitted to exercise his developing skills and feelings and we, therefore, speak of psychologic needs just as we speak of nutritional needs. Similarly, we may speak of psychologic

deficiency disease when a child is deprived of psychologic gratification, analogous to nutritional deficiency disease when a child is deprived of a proper diet.

From a practical standpoint, this means that a child may be injured psychologically and have disturbances of behavior if we attempt to interfere with his developmental plan either by trying to hurry him or retard him, or by failing to allow gratification for his psychologic needs, or by overindulging his needs. It is obvious, therefore, that a knowledge of psychologic growth and development is just as necessary for proper child care as is a knowledge of physical growth and development.

Discussion

Dr Daniel P Peeler, *Rochester, New York*—This splendid paper we have just listened to is very timely and is of great interest to us all.

There has been a great deal appearing in the literature lately about various standards that we should use in determining the normality or abnormality of our little charges, and it appears to me that a great deal of this scientific work is not practicable or applicable to those of us in actual pediatric practice, for we would need a staff of workers and an office of equipment that would be financially impossible to maintain.

Unfortunately, through the radio and through pamphlets, much has reached the laity that is disturbing beyond words, not only to physicians but to parents as well. There is not one of us who has not been presented with just such a problem, where the parents have not taken into consideration the child as a whole unit such as the authors of this splendid paper have presented to us this morning.

In order to arrive at a correct impression of the individual we must have not only some conception of the individuals comprising his or her age group, but it is also essential that we should know something of the environment in which the child lives, the hereditary background which plays a very important role. For example, if we, by digging, can pry loose from the parents the fact that it has been a familial characteristic for the various individuals in their antecedents to be small in stature and undernourished during early childhood or vice versa, then we are able not only to reassure the parents, but are able to have for ourselves a better understanding of what to expect in growth and development for this individual child.

Dietary intake is one of the best guides to understanding the growth and nutrition of our charges and, unfortunately, too many times the busy pediatrician overlooks this important factor. A useful method to obtain this is to ask the mother to keep track of the child's meals for a week, as to articles and quantities of food taken. This will prove illuminating not only to the physician, but to the parents as well.

We have set up standards for the mental growth and development of the child which must also be carefully used lest we cause unnecessary worry and heartaches for our parents. It has been customary in early childhood to take the times of sitting, teething, walking, talking, and the like—which are physical growths—as a rough measurement of what to expect from the child as to mental development later on. Here also the factors brought out by the Doctors Bakwin must be considered, that is, race, sex, environment, heredity, and dietary regimen. For all of these go hand in hand to make up the individual and before we venture an opinion the child as a whole must be carefully studied. The tendency to overlook these factors is one great weakness of the psychologists.

Will you bear with me while I cite a case? A boy of 2 years of age was first seen in our Child Guidance Clinic for feeding problem and enuresis. Parents were unsuited to each other and there was much conflict in home, mother was unstable, child was pale, undernourished, closely attached to mother who waited upon him and gave into his every whim, at the same time showing definite rejection. Child developed impetigo, had to be hospitalized to clear up. Child did not develop normally—either physically or mentally. He was seen again four years later because of poor physique and nonprogression in his school work. At this time, he was placed in a rural foster home where by skillful handling both in the home and in the school, the boy, within two years, was on the honor roll in his school grade, up to the placement as to age, and, physically, was a normal, robust boy.

Before closing, I should like to ask Dr Bakwin how he interprets the findings of Jeans and his co-workers, namely, that the intake of vitamin "D" has a definite effect upon the linear growth of the infant when taken in amounts of 340 to 600 units daily.

Dr William S Langford, *New York City*—I shall discuss this paper from the aspect of the more psychologic factors in the growth and development of children. As Dr Bakwin has indicated, in order to deal successfully with

children the practitioner of pediatrics must be familiar with both the physical and psychologic aspects of growth and development in children. This knowledge is of greatest importance in the prevention of emotional maladjustments in childhood. The prevention of such difficulties is an important aspect of the practice of pediatrics. It is in this sphere that the pediatrician may well be of greatest service to the children who are brought to him. Here, as always, an ounce of prevention is worth a pound of cure and certainly the treatment of a well-developed personality disorder may tax the resources and ingenuity of a skillful psychiatrist.

I should like to stress some of the preventative work that can be done in pediatric practice in connection with the routine visits of the infant and child for periodic examinations and advice as to general hygiene. It is well not to attempt too much in the sphere of mental hygiene when the parent is agitated and anxious over an acute physical disease. Such advice should be given with a thorough knowledge and understanding not only of psychologic and emotional growth and development, but also of physical growth and development. Dr. Bakwin has wisely stressed the importance of the child's fundamental need to be considered a unique individual and to be permitted to grow and develop at his own rate of speed. Much unhappiness in childhood and later life can be avoided if we help parents to remember this basic principle. The child, then, will not be used as the means with which the parents keep up with the Joneses (or even attempt to surpass them) in matters of weight gain, time of walking, talking, or teething, and in earliness of toilet training, or as the outlet for satisfying their own earlier, thwarted ambitions. In the latter case the child is often pushed into a vocation which he dislikes and for which he shows no aptitude. Feeding difficulties can often be prevented by the alert

pediatrician who sees the mother's tendency to stuff and force food into the unwilling child so that he may gain more rapidly. He can prepare the parent for changes in rate of weight gain. He can help the parent or nurse make the weaning from breast or bottle to the cup a less traumatic experience than it usually is. The method of administering the food is just as much the physician's business as is the type or quantity of the food. Toilet training may be poorly handled and serve as a focus out of which develop personality difficulties in the child or even deep-seated resentments which interfere with the normal development and progression of parent-child relationships. As a rule, it is begun too early and the failure of the child is interpreted as stubbornness. The optimal time for beginning toilet training varies in different children, once the child is ready, provided methods are not too harsh or unwise, it is likely to proceed quite satisfactorily. It should not, on the other hand, be begun too late, as it may then coincide with the negativistic period which starts in most children at the end of the second year. This period normally lasts a few months and causes parents a good deal of concern. They can be prepared to expect its coming and be helped to handle it constructively. The constant "no, no" of the child, his increased irritability and tendency to do things by opposites are best handled by ignoring the petty "no" and "I won't" replies and at the same time insisting on matters of daily routine with gentle firmness. So-called "reasoning" with the child serves only to intensify his resistiveness. Demands on the child should be reasonable and all semblance of a power contest avoided. The child needs the same good-natured sympathetic attitudes and encouragement that are indicated in all contacts with children who are constantly learning new things and needing to develop new capacities.

A DANGEROUS ENEMY

We hear a great deal these days about enthusiastic "left wingers" who would radically alter the present methods of medical practice. Among this group are ardent supporters of compulsory health insurance, government or privately subsidized medicine and out-and-out state-controlled and supervised medical practice. Not a few of these proponents of change are offensively vocal, principally because they are uninformed. Of course, not all of those who favor changes in medical practice are radicals but those who are take advantage of every opportunity to urge their cause. Then, too, there is a small minority group in the profession itself which favors pro-

posals as "radical" as any already advanced.

Disturbing as have been the activities of these enemies of the present system of medical care, it is our opinion, declares the editor of the *Medical Annals of the District of Columbia*, that they are far less dangerous to the future of medicine than the indifferent medical practitioner. If there were only a few of such practitioners it would not be serious. The difficulty lies in the fact that they constitute a large segment of the profession.

Nothing is as deadly as indifference. Nothing is more difficult to combat. There is at least a chance for accomplishment where there is opposition but what can one do in the face of inertia!

ROENTGEN RAY THERAPY OF ACUTE MASTITIS DURING LACTATION

HARRIET C MCINTOSH, M D , New York City

(From the Woman's Hospital)

TREATMENT of acute and chronic inflammatory conditions by exposure to roentgen rays is not new. It was tried sporadically and experimentally from the earliest days of roentgen therapy, and in recent years its value has been widely recognized in a variety of conditions—erysipelas, furuncles, and carbuncles, cellulitis, tuberculous adenitis—to name but a few. Numerous contributions on the general topic have appeared, notably by Hodges^{1,2,3} and by Desjardins,⁴ but no specific study on irradiation of acute mastitis has yet been published in this country. In February of this year, Elward and Dodek⁵ presented a paper before the Postgraduate Clinic of the Medical School of George Washington University, reporting on 25 cases and giving a review of the literature. As their paper is to be published shortly, I shall not attempt to include here any general discussion of this literature, but refer to it only when needed for comparison with my own material.

My report comprises 44 cases treated in 1938 and the first three months of 1939. Most, if not all, of the symptoms of redness, heat, swelling, induration, pain, and fever were present in all cases of the group. Simple engorgement of the breasts, no matter how painful, was not treated by roentgen therapy. It is the experience of all practicing obstetricians that a large proportion of cases of acute puerperal mastitis subside spontaneously or by the use of the usual palliative ice bags and supporting binders. In this series of cases the only treatment has been supporting binders plus fractional x-ray irradiation. If, in spite of this treatment, the process progressed to active suppura-

tion, the abscess was incised and then drained in accordance with the usual surgical procedure. All cases subsequently healed. The advantages of x-ray treatment to be set forth herein are as follows:

- 1 Prompt relief of patient's symptoms, particularly pain.

- 2 Seemingly more rapid resolution of the inflammation, though comparisons of course are difficult to prove.

- 3 If suppuration is inevitable, x-ray tends to limit and more definitely demarcate the process, hastens fluctuation, and after incision accelerates healing.

- 4 Percentage of cases suppurating is lowered slightly in our total series, and markedly in those receiving optimum treatment.

A young woman physician with a five month-old baby, whom she was nursing, presented herself one morning in the x-ray department, saying that her breast felt sore on arising and had become rapidly more painful during the forenoon. On examination there was found a red, indurated, exquisitely tender area about 12 by 10 cm in diameter in the outer hemisphere of the right breast. She was given the usual small dose of x-ray and sent home to bed. She returned to work in the hospital the next morning with this report. On reaching home after treatment, her temperature was 101 F and she was in great pain. She went to bed and slept for three hours. On waking, her temperature was 100 F, her breast uncomfortable, but not actually painful. At 9 00 P M her temperature was 99 F, her breast tender to the touch, but with no pain. Second day examination showed induration diminished by two-thirds, redness gone, tenderness slight, tem-

Read at the Annual Meeting of the Medical Society of the State of New York, Syracuse, April 25, 1939

perature normal, no pain whatever. A second treatment was given for safety and there has been no recurrence.

All patients do not resolve as rapidly as this. The case is used here to illustrate the optimum result, and also because the patient, as a physician, was a trained observer and an unusually reliable reporter of symptoms. The means by which small doses of x-ray affect inflammation is not well understood. It is known that white cells, leukocytes, and particularly lymphocytes, are especially sensitive to irradiation. The theory is rather generally advanced that alteration or destruction of these cells gives off some ferment, antibody, or other product of molecular ionization which tends to inhibit or resolve, by phagocytic or chemical action, the inflammatory process.

The Woman's Hospital for the three years, 1936-1938, had 4,568 deliveries. Of these, 152 had nonsuppurative puerperal mastitis, and 35, or 0.7 per cent, had breast abscess. This percentage corresponds closely to that of 0.55 per cent reported by Dippel and Johnston⁶ in a study of 20,258 women from the Obstetrical Service of the Johns Hopkins Hospital between 1896 and 1934. On the basis of this close correspondence and the large numbers involved, our material can, I think, be considered typical of good hospital practice, at least for this country. In trying to evaluate the effect of x-ray treatment on suppuration, I took the years 1936 and 1937, when no x-ray was given, and 1938, when it was given on some cases and not others, and then added the cases treated so far this year (see Table 1).

On the basis of this chart the gross improvement of the single factor of suppuration does not seem significant, but the x-rayed cases are few. Taking the entire number of 44 treated in 1938 and 1939, 9 or 20 per cent, abscessed, but 4 of these were at the point of fluctuation when treated—the treatment being given to hasten the process—so that it was not possible to “save” the breast. If one might be allowed to consider the other 5 as a fair trial, and failure, of x-ray to

TABLE 1—ACUTE PUERPERAL MASTITIS
Comparative Table with and without X-ray Treatment

Year	Total Cases	Non-suppurative	Suppurative	Percentage Suppurating	X-ray Treatment
1936	64	51	13	20	0
1937	46	37	9	20	0
1938	52	43	9	17.3	0
1938	25	21	4	16	X
1938 & 3 mo 1939	44	35	9	20	X
Breasts not fluctuant at first treatment	46*	41	5	10.8	X
Breasts treated in first 24 hrs after onset	36*	35	1	2.7	X

* Figures refer to total breasts, not total patients. Six of 44 patients had bilateral involvement, hence 50 breasts treated. Of bilateral cases 2 developed abscess in a single breast.

prevent suppuration, that would cut the failures to 10.8 per cent, much lower than any of the above percentages. Further consideration of the abscess cases and of other factors in resolution will be given below.

As this is an obstetrical and not a roentgenologic gathering, I shall give only the two most important factors of my technic, namely:

1 Small individual doses, 50 to 60 roentgens at a time.

2 Low, rather than high voltage, in the range of 120 to 125 kilovolts, with aluminum filtration.

This quality and quantity of radiation seems to me ample. Even with six treatments, the most I have ever given (to 2 patients), the amount reaching the skin is far below a threshold erythema, and the amount reaching the underlying lung is negligible. I sometimes give 75 roentgens if the treatment portal is very small. Some workers give considerably more treatment than I have described, and it is true that with these small amounts of x-ray there is considerable leeway. But I feel that in such a benign condition the minimum amount of effective treatment is most to be desired.

The number of treatments necessary shows wide variation. Thirty-eight patients had one breast involved, 6 had two, hence there was a total of fifty breasts treated among 44 individuals. In the single-breast group, 15 had one treatment, 12 had two, 5 had three, and 6 had from four to six treatments. Of the 6

patients with bilateral involvement, 1 had a single treatment to each breast, another required one treatment to one breast and three to the other, the remainder varied between two and five treatments. Where more than one or two treatments were given, the field exposed to the rays was gradually reduced. A large, red, indurated area requiring a skin portal 12 by 14 cm on the first treatment might call for a 7 by 7 cm portal on the third, perhaps a 4 by 4 cm portal on a possible fourth round—the purpose of the latter being to help resolve a small indurated central core, even though fever, redness, and pain had already disappeared. Margraf, quoted by Elward and Dodek, stated that he had 61 per cent resolutions if one or two treatments were required, 33 per cent with three treatments, and that treatments beyond three were of no value. I have not found this to be the case, but his percentage of resolution in all classes is low.

The most important thing, judging by this group, is not the number of treatments applied, but how early the treatment is started. Thirty-six breasts were referred for treatment within twenty-four hours of the onset of the chief symptoms—fever, redness, induration, and pain. Of these only one, or 2.7 per cent, suppurated (see Table 1). All the rest recovered promptly. The one which did not was one of the first cases treated. She received a single treatment, her acute symptoms subsided within two days, and she was discharged in four days, with a tiny area of induration remaining in the center of the previously involved area. She returned a week later with a small abscess in this location. She should have had more treatment. The abscess was incised and healed promptly. Of the remaining 35 cases, 18 required only one treatment for complete resolution, with no recurrences. The others required for the most part two or three treatments.

Fourteen breasts were sent for treatment from forty-eight hours to five days after onset of the mastitis. Of these eight

suppurated, or 57 per cent. However, four of the eight were practically or entirely fluctuant when first seen. Excluding these, we have ten breasts in the group sent late, with four going to supuration, or 40 per cent. Statistically, it would appear that roentgen treatment was of little avail unless instituted early. Nevertheless, because of enthusiastic cooperation in the Woman's Hospital, I have a much larger group of early than of late cases, and of the late ones, six did actually resolve without going to abscess.

Furthermore, it is my impression that the suppurative cases that had received x-ray treatment healed more promptly than at least some of those that did not. In looking over a series of Woman's Hospital charts of breast abscess, I find frequent notes of second, and occasionally of third admissions, that is, two admissions for incision of one or more abscesses in a breast. Dippel and Johnston, in their series of 113 breast abscesses, report second operations on as high as 26.55 per cent. The following case is interesting in this connection.

A primipara, aged 23, had two successive abscesses in her left breast, at three and four weeks, respectively, after delivery. She was given no x-ray treatment on the breast at any time. Both abscesses were incised and drained. Seven weeks after delivery she returned to the follow-up clinic with mastitis in the right breast and was referred for x-ray treatment. She presented a hard, tender, reddened area about 8 by 8 cm, with a small fluctuant center. She was given five treatments of 50 roentgens each, in seven days. After the third treatment, the small softened center opened spontaneously, and within a week the surrounding induration had absorbed and the tiny central abscess had healed. The two incised abscesses in the opposite breast were still draining after almost a month.

A number of other observations made by writers on this topic seem to me to bear more on the subject of mastitis in general than on the x-ray treatment of it, so I shall enumerate them but

briefly The series comprised 24 primiparas and 20 multiparas The oldest was 37, youngest 18, average age 26.8 The right side was involved in 20 cases, left in 18, both in 6 Six of the 9 abscess cases had culture reports, with staphylococcus albus in 4, aureus in 2 This number is too small to have meaning Dippel and Johnston report 40 aureus and 7 albus out of 60 cultures The time of onset after delivery showed nothing of significance except a predilection for the tenth and eleventh days, when there were 16 cases A single case occurred two months before delivery, and there were 7 after the third week, the latest, at five months, being described above. Twenty-five came within the first two weeks Double breast involvement was more recalcitrant to treatment, in the sense that a higher average of treatments per breast was required, and in 2 of the cases, one of the breasts abscessed In the remaining 4 double breast cases, both sides resolved

The matter of continuing lactation depends on the preference of the attending obstetrician, also on how early the case is referred for treatment, and how quickly responsive it proves to be. Where a case is treated in less than twenty-four hours from onset and resolves with one treatment, no interruption may be necessary, or interruption

for one or two nursings Where there is a large area of involvement that does not respond to a first treatment, drying of the breast is usually preferred A few women requiring multiple treatments have insisted on nursing their babies and have done so successfully

Summary

Roentgen treatment of acute mastitis during lactation presents the following advantages

- 1 Prompt relief of pain
- 2 Shortened duration of the process
- 3 Striking diminution in number of cases going on to suppuration if treated within the first twenty-four hours—27 per cent in this series, against an average of 18 per cent to 20 per cent in non-treated material
4. If suppuration occurs, more prompt localization of the process and a shortened period of healing

THE FAMILY DOCTOR

For my part I am still unconvinced that the family doctor is an anachronism I still want somebody to save me from unsuitable or excessive specialist advice, I need someone to coordinate the findings of specialists and discount them if necessary, and above all I want someone who is willing to talk to me, at length, about my migraine, my little boy's delinquencies, my wife's recent strangeness, my baby's inoculation, and my daughter's desire to marry a man with asthma.—*Onlooker, Lancet*

WELL-MERITED BOUQUET

The *Detroit Medical News*, in an appreciative review of Dwight Anderson's *What It Means to Be a Doctor*, says "During recent years, some of the best material in medical-public relations has come from the New York Society's Bureau, and from the pen and mind of Dwight Anderson. This sprightly little book, his latest effort, is the story of a medical student and the beginnings of his practice It would be an appropriate addition to the practitioner's waiting-room table."

It is not unscientific, as some scientists seem to believe, for even a scientist to make his meaning clear.—*Albert E. Wiggam*

In no profession does culture count for so much as in medicine, and no man needs it more than the general practitioner.—*Sir William Osler*

PSORIASIS—WHAT TO DO ABOUT IT

HERBERT H BAUCKUS, M D , Buffalo, and ALBIN V KWAK, M D , Depew, New York

PSORIASIS is an old and common cutaneous disorder dating from antiquity. Its etiology and treatment are admittedly controversial. While psoriasis has an unknown etiology in which heredity possibly plays some part, there is some knowledge relating to the occurrence of this disease. The majority of patients are well except for skin manifestations. There are, of course, reasons pro and con as to whether or not it is an infectious disease.

Examination of literature discloses many curative agents and a varied local and general therapy proposed to combat this disease. Time-worn are the phrases describing psoriasis as dry, scaly dermatitis with rings and gyrate figures occurring in certain related areas of the body. A statement to the patient that he has an incurable disease, although a relatively harmless one, will later merit consideration. It may sound rather bold to say that atypical psoriasis is more prevalent than the characteristic form. Probably that is so because unusual cases come to the attention of the skin specialist, and ultimately most cases of psoriasis are seen by the dermatologist. Many, to be sure, have been affected by previous treatment.

The unusual manifestations of psoriasis demand early recognition in this disease. This is especially so in cases in which the scalp is involved. There is some relatively causative, unknown factor to be explained where we see a real seborrheic dermatitis with inflammation and exudation extending to the face and ears, and it is not until some years later that typical psoriatic lesions are found. Is this transition or so-called transformation some manifestation of an allergic or metabolic process? Some may question this and call it a mistaken diagnosis. It is a known fact that such lesions are early recognized

as seborrheic but only later on assume the psoriatic role.¹

Just as we have the seborrheic element involving the scalp and postaural areas, so do we have the counterpart which is the sudaminal element in the hands, soles of the feet, axillae, perineum, and the intertriginous areas. The lesions of the palms and soles develop fissures and exudation. We are all familiar with psoriatic lesions of the perineum and groin that have to do with psoriatic lesions of typical, characteristic distribution elsewhere. But we also see many cases in which lesions are quite different, characterized by a great reaction causing itching, exudation, and general inflammation. Some of these cases are mycotic, and some are mixed types of infections—infectious eczematoid dermatitis, occupational dermatosis, palmar and plantar syphilides. Most of the dermatologists agree that there are cases of pustular psoriasis. Special attention is needed for lesions of male genitalia and natal cleft. Lesions of the mucosa appearing on glans penis occur more often than is popularly supposed. Cases have been reported of psoriasis followed by mycosis fungoides. Its relation to cancer and trauma and various other aspects have been discussed in the literature. Some of the so-called seborrheic eczemas of the ear canals are really psoriasis, and we have one case of a definite psoriatic lesion encroaching upon the tympanum.

This disease may be present alone from the beginning, or perhaps in association with other skin disturbances later leaving a psoriatic predominance. Also there is a universal belief that arthritis may be a part of a psoriatic syndrome. This arthritis usually affects more than one joint, and this subject requires a great deal of investigation. There are cases of acute gen-

*Read at the Annual Meeting of the Medical Society of the State of New York,
Syracuse, April 27, 1939*

eralized dermatitis which later leave typical psoriatic patches. While the microscopic pathology of psoriasis is quite definite, these examples of inflammatory reactions are quite difficult and sometimes impossible for the dermatopathologist.

To combat this disease we should use the methods that will result in a minimum of annoyance and discomfort to the patient. Methods must be suitable to the patient, and all the areas affected must be treated, especially the exposed areas—namely, the face, hands, and scalp. Because this disease is so inconstant and variable, it may require different methods of attack for the various locations that may be involved with psoriasis. Certain types of remedies work better on certain areas of the body. The study of bizarre manifestations of psoriasis and the examination of those cases in which apparently nonpsoriatic lesions develop into typical psoriasis, may give us some clues as to the cause and the methods of evolution of this puzzling disease.

We would like to call attention to the following salient features of our treatment of psoriasis. We have found that acute generalized psoriasis even in the incipient stages, especially in children, should be treated with soothing applications instead of stimulation. Rest in bed, avoidance of irritation by pressure of clothing and mechanical appliances, freedom from irritation from various causes including occupation, serve to enhance the healing process. Overtreatment and early use of stimulating ointments may result in complications. Cleanliness cannot be overrated, especially for the scaly, crusted, thickened areas. Stimulants such as ammoniated mercury, sulfur, and the tar groups should be confined only to the patches themselves and should not be applied to the unaffected parts because of the possible consequent dermatitis. At this stage, chrysarobin and the newer similar products should be avoided. There is no uniform conventional prescription for this disorder. This is apparent, since psoriasis affects not only the glabrous skin and nails, but

also areas of the skin with hair and oil glands, and the areas with sweat glands such as the chafing of the intertriginous areas of the breasts, perineum, groin, also the hands, feet, and the mucous membranes. Because of the essential parts involved, these will require a special type of treatment adapted to the particular location. Hence the necessity that psoriasis be treated according to the location of the lesions.

One of the most important things is to get the patient to persist in treatment for the proper time—even when but a few areas remain. If patients continue treatment they are much more apt to avoid the severely crusted, fissured, and indurated lesions seen in irregular therapy. Many psoriasis patients have been discouraged over the poor prospect of a complete cure and have been given to understand that they must expect to carry more or less lesions for considerable periods of time. We feel that this is the wrong attitude and that the psoriasis patients should be so handled that they persevere in their routine of treatment. If this is done, patches of chronic, indurated lesions will seldom be seen. We wish to emphasize that the reappearance of even a few or relatively mild lesions should be the signal for immediate treatment with the proper local applications. This method is most apt to result in the final cure. This has been to us, the most satisfactory item of our experience in dealing with this chronic disease. This method entails no more visits to the dermatologist than do the sporadic attempts made to treat the lesions that have been allowed to develop for a considerable length of time.

Much can be done for psoriasis of the scalp and the accompanying borderline lesions of the face. The safest and best ointment for the scalp is a 20 per cent ammoniated mercury in Ungt. aq. rosae. The ointment is applied to the skin by parting the hair in the various areas. The patient is told to wash it out in twelve to twenty-four hours. This increases cleanliness, and unquestionably soap and water help a great deal in psoria-

PSORIASIS—WHAT TO DO ABOUT IT

HERBERT H BAUCKUS, M D , Buffalo, and ALBIN V KWAK, M D , Depew, New York

PSORIASIS is an old and common cutaneous disorder dating from antiquity. Its etiology and treatment are admittedly controversial. While psoriasis has an unknown etiology in which heredity possibly plays some part, there is some knowledge relating to the occurrence of this disease. The majority of patients are well except for skin manifestations. There are, of course, reasons pro and con as to whether or not it is an infectious disease.

Examination of literature discloses many curative agents and a varied local and general therapy proposed to combat this disease. Time-worn are the phrases describing psoriasis as dry, scaly dermatitis with rings and gyrate figures occurring in certain related areas of the body. A statement to the patient that he has an incurable disease, although a relatively harmless one, will later merit consideration. It may sound rather bold to say that atypical psoriasis is more prevalent than the characteristic form. Probably that is so because unusual cases come to the attention of the skin specialist, and ultimately most cases of psoriasis are seen by the dermatologist. Many, to be sure, have been affected by previous treatment.

The unusual manifestations of psoriasis demand early recognition in this disease. This is especially so in cases in which the scalp is involved. There is some relatively causative, unknown factor to be explained where we see a real seborrheic dermatitis with inflammation and exudation extending to the face and ears, and it is not until some years later that typical psoriatic lesions are found. Is this transition or so-called transformation some manifestation of an allergic or metabolic process? Some may question this and call it a mistaken diagnosis. It is a known fact that such lesions are early recognized

as seborrheic but only later on assume the psoriatic role.¹

Just as we have the seborrheic element involving the scalp and postaural areas, so do we have the counterpart which is the sudaminal element in the hands, soles of the feet, axillae, perineum, and the intertriginous areas. The lesions of the palms and soles develop fissures and exudation. We are all familiar with psoriatic lesions of the perineum and groin that have to do with psoriatic lesions of typical, characteristic distribution elsewhere. But we also see many cases in which lesions are quite different, characterized by a great reaction causing itching, exudation, and general inflammation. Some of these cases are mycotic, and some are mixed types of infections—infectious eczematoid dermatitis, occupational dermatosis, palmar and plantar syphilides. Most of the dermatologists agree that there are cases of pustular psoriasis. Special attention is needed for lesions of male genitalia and natal cleft. Lesions of the mucosa appearing on glans penis occur more often than is popularly supposed. Cases have been reported of psoriasis followed by mycosis fungoides. Its relation to cancer and trauma and various other aspects have been discussed in the literature. Some of the so-called seborrheic eczemas of the ear canals are really psoriasis, and we have one case of a definite psoriatic lesion encroaching upon the tympanum.

This disease may be present alone from the beginning, or perhaps in association with other skin disturbances later leaving a psoriatic predominance. Also there is a universal belief that arthritis may be a part of a psoriatic syndrome. This arthritis usually affects more than one joint, and this subject requires a great deal of investigation. There are cases of acute gen-

*Read at the Annual Meeting of the Medical Society of the State of New York,
Syracuse, April 27, 1939*

a grateful response. For psoriasis of the glabrous skin, we alternate the soap treatment with ointment, when indicated, containing the usual stimulants, but with the idea of avoiding more than a mild irritation. It does not appear to us that psoriasis lesions should be very drastically treated and inflamed. Symptoms of irritation should make us think quite early that we do not want to encourage a dermatitis exfoliativa.

We have, of course, used the combined crude coal tar and ultra-violet lamp treatment.² Patients do not like to attend to daily treatment, and we believe that much of the good of this method comes from the fact that patients are using applications regularly. We are not so much impressed with the idea that combination of ultra-violet ray and crude coal tar has some special efficacy. To be sure, ultra-violet ray helps psoriasis. However, this seems to be much more effective when the patient is exposed to outdoor sunlight and is indulging in exercise.³ We have mentioned x-ray. Of course we do not cure psoriasis with x-ray, and we do not give general or regular treatments with it. If x-ray is used more than a few times, its remarkable effect wanes. We, therefore, "save" x-ray and reserve it for the occasionally "sudden thrust" to the unsightly lesions of the face, the borderline area of the scalp, nails, palms, and for giving great comfort to the inflamed lesions of the intertriginous areas. As in most diseases of the skin, x-ray has its place as an adjunct to therapy and not as the sole treatment.

In this paper, we have given little attention to internal treatment.⁴ If we have been impressed at all with the dieting measures it has been with the idea that milk is of some value. There are, of course, various reasons for this. We think that reduction of weight is of obvious value in certain patients with psoriasis in the intertriginous areas, and this point may be a most practical one. The reactions to fever temperature caused by various means are sometimes striking. We have an idea that the effect here is really a local one and is not due to any

internal metabolic change. Injection of various proteins—blood, scales, milk, etc.—sometimes produces results which, however, are temporary.⁵ Vitamin therapy, either with or without local treatment, has not given us enough evidence to evaluate its use.⁶ It seems that arsenicals are now in an unpopular stage, and they, of course, have done harm. It may be said that almost any internal product has been tried in the internal treatment of psoriasis—that speaks for itself. Of course, there is the patient who gets well without treatment, but there is a cause for that and we should study that phenomenon.

What to do about psoriasis? Let us welcome the patient with it and treat him as a challenge to our resourcefulness and not as a weary burden inflicted upon us. If we study and treat each psoriasis patient as an individual problem and not as someone that we dismiss with a prescription for a one-half strength tube of anthralin or some newer product—then we will be giving our public a practical illustration of the value of dermatologic knowledge. Knowing so little about psoriasis, we treat it more with art than with science, not forgetting the need of science for research on this disease. The young dermatologist sometimes does not realize it, but he has in psoriasis his everyday opportunity to show what kind of a practicing physician he is. We hope that these simple observations and suggestions may stimulate a more expectant attitude in our work with psoriasis.

Discussion

Dr Rudolph Ruedemann, Jr, Albany—This interesting paper should provoke considerable discussion.

The prevalence of this unsightly eruption, its unknown etiology, and the fact that there are no definite treatment methods that will give us the desired results, make this dermatosis the "bugaboo" of the dermatologists.

sis This ointment may be used once or twice a week after the lesions have largely disappeared, then the frequency of application may be lessened. However, the patient who has had psoriasis of the scalp should use such an ointment once in two to four weeks, even when he is free of all lesions. We seldom find recurrences in the scalp if this regimen is adhered to. Furthermore, it keeps the scalp in good condition as to the seborrheic scaling and similar disturbance. We find that a 1 per cent salicylic acid in 50 per cent alcohol used each night between ointment application is clean, soothing, and very effective. A 3 per cent to 5 per cent liquor carbonis detergens may be added to this. Practically no other drugs are necessary for treatment of scalp psoriasis. We use the x-ray for one or two treatments to the heavy lesions of the scalp and especially for the lesions of the face. The dosage used does not endanger alopecia. If there is an accompanying seborrheic crusting around the ears we use wet dressings.

Psoriasis in the intertriginous areas of the breasts, axillae, perineum, natal cleft, and on the scrotum and glans penis, is best treated by use of wet dressings and frequent use of soap and water. A thorough lathering is desirable and we think there is some advantage in tar soap. If the patient is encouraged to wash thoroughly with a well-soaped wash cloth in the perineum and groin morning and night it will be found most effective. We have found that many patients neglecting this observance have constantly recurring trouble. If an ointment is prescribed it should be one of ammoniated mercury, sulfur, or crude coal tar, and should be worked in at nighttime and immediately wiped off. We do not have the patients walk about when the ointment is applied. The parts are to be well powdered when the patient is up and about. We do not use salicylic acid or any of the chrysarobin groups in these areas. This may be the place to mention that we feel that regular soapy applications are good for psoriasis in any area, granted that a real eczematous dermatitis is not present

and the patient is not sensitized to soap. When we come to the treatment of the dry indurated lesions we find that alternating applications of soap and water and ointments are most effective. In any skin disease, application of an ointment to any indurated or chronically affected area is much more effective if it follows immediately after wet dressings have been used continuously for an hour or two.

This wet dressing process is especially effective in the treatment of obstinate lesions of the palms and soles. The palmar lesions of psoriasis are, of course, sometimes not easily diagnosed. Every dermatologist has seen what he has considered an eczematous infiltration change into one he can recognize as psoriasis. Ringworm and syphilis are not so difficult to differentiate. One should always suspect persistent palmar lesions to be psoriasis. The nails may give some clue to diagnosis. Often, occupation irritating the psoriasis and causing some pressure keratinization becomes a complicating factor and leads one to miss the psoriasis diagnosis. We find that in this type of palm a preliminary dose of x-ray, possibly repeated in one month, gives a local application the best opportunity to succeed. We find that a 5 per cent salicylic acid added to a 5 per cent crude coal tar ointment worked into the palm and then wiped off is the most effective local treatment. It is best applied at night, and in obstinate cases it is used following a wet dressing. It is well to remember that pressure always aggravates psoriasis. These patients should wear gloves and avoid all irritation if possible. There are, to be sure, many other applications that are useful, but we have never found any that compare with this scheme of treatment.

The psoriatic nail should be softened by applications of salicylic acid or ammoniated mercury applied overnight under finger cots. Here, x-ray is definitely of value. In women who have the mild and yet annoying cosmetic lesion of the finger nails, the use of x-ray and radium at very infrequent intervals secures

a grateful response For psoriasis of the glabrous skin, we alternate the soap treatment with ointment, when indicated, containing the usual stimulants, but with the idea of avoiding more than a mild irritation It does not appear to us that psoriasis lesions should be very drastically treated and inflamed Symptoms of irritation should make us think quite early that we do not want to encourage a dermatitis exfoliativa

Discussion

Dr Rudolph Ruedemann, Jr, Albany—This interesting paper should provoke considerable discussion

The prevalence of this unsightly eruption its unknown etiology, and the fact that there are no definite treatment methods that will give us the desired results, make this dermatosis the "bugaboo" of the dermatologists

One point that this paper brings up seems worth emphasizing—the attitude one is prone to assume when he sees a patient with psoriasis. He gives rather an unfavorable prognosis, does not encourage the patient as to the treatment results, and the patient feels immediately the hopelessness of the situation. These patients are definitely discouraged at the outset because the disease tends to recur. They have gone from one doctor to another, and they find it rather difficult to convince people with whom they work that it is not contagious.

Then we so often see the patient who has been overtreated. The eruption has been precipitated into a generalized dermatitis. In spite of repeated warnings, we still see palmar "arsenical-keratosis" following the prolonged use of Fow-

ler's Solution. X-ray and radium do give marvelous results in solitary lesions—perineal and perianal regions—but they are dangerous weapons in the hands of those not familiar with the aftereffects. One still sees x-ray dermatitis with its deplorable atrophy and atrophic ulcers, resulting from misjudgment on the part of the x-ray therapist.

The treatment of psoriasis is still a gamble but we have at our disposal various methods of treatment with which results may be attained, and we may assure the patient of some relief.

I believe that it is up to us to encourage the patient. If the dermatologist cannot get results, it is not our purpose to drive these patients who like the drowning man are willing to grasp at a straw, into the hands of a charlatan.

GOOD TASTE IN SIGNS

"Are Neon signs ethical?" This question was raised recently by several physicians in Indiana, and was referred by the Indiana State Medical Association to its Bureau of Publicity, which was authorized by the House of Delegates of that Association to give opinions on certain matters involving the principles of medical ethics.

Here's what the Bureau said:

"Of course a great deal depends upon the size, the location, and the prominence of such signs. A sign does not have to be a neon sign to be in bad taste. Lettering on an office window or a door which is over-conspicuous in size or in coloring is bad taste and hence unethical. If all the physicians in a town use a sign of the same size it would not be unethical, but if one physician used a neon sign and the others did not use neon signs, that would give undue prominence to one physician's name, and hence the Bureau feels that the use of a neon sign in this instance would be a breach of local custom and therefore unethical."

In our opinion, the Bureau hit the nail on the head when it said:

"A sign does not have to be a neon sign to be in bad taste." Have you ever noticed a sign out side a physician's office which was far from being in good taste? We have.

The Principles of Medical Ethics of the American Medical Association states in Chapter 3, Section 4, "It is unprofessional to employ any methods to gain the attention of the public for the purpose of obtaining patients." In that same section also appears the following: "The most worthy and effective advertisement possible, even for a young physician, and especially with his brother physicians, is the establishment of a well-merited reputation for professional ability and fidelity." This is a fundamental truism in ethics.

"John G. Jones, M. D.," a plain, dignified, in conspicuous, lettered sign, without embellishments, in our opinion is the only appropriate sign for a physician.—*Ohio State M. J.*

TUBERCULOSIS IN ELDERLY PEOPLE

It is a well-known fact that the tuberculosis death rate is high among young people but many do not realize that it is also very high among old people. There are more cases of tuberculosis among those persons in the twenties than in the teens, more among those in the thirties than in the twenties, and at the age of fifty, for the number of persons living, the incidence of reinfection type of tuberculosis is higher than any other period of life. Every elderly person who has frequent colds, a so-called chronic bronchitis or asthma, should have a careful chest examination. Because of an atypical type seen in older people repeated sputum examination should be made. Due to the frequency of tuberculosis in this group and their intimate contact with children, considerable infection is spread by them.—*John E. Nelson, M. D., Seattle, Wash. Northwest Med*

COOK IT THOROUGHLY

Improperly cooked pork is believed to have been responsible for 9 cases of trichinosis which occurred among persons who attended a church supper in Potsdam, St. Lawrence County.

Seven of those affected became ill between November 1 and 15, and 2 cases developed more recently. All nine had partaken of a pancake and pork sausage supper which was served October 25 to about one hundred persons. All had eaten the sausage and three stated that they had eaten no other pork recently. The pork from which the sausage was made was obtained from one individual whose pigs are fed raw garbage collected in the village of Potsdam.

Fresh pork, provided it is thoroughly cooked, is a safe food. Thorough cooking will destroy any trichina worms that may be encysted in the meat.

THE TEACHING AND PRACTICE OF NEUROLOGY AND PSYCHIATRY IN THE OUTPATIENT DEPARTMENT

NOBLE R CHAMBERS, M D , Syracuse, N Y

ONE of the notable changes in modern medical teaching is in the increasing use of the dispensary or outpatient department for such purpose. The writer's experience dates back to 1918-1920 as a student, 1921-1923 as an intern and postgraduate student, and since January, 1924, as a neuropsychiatrist in private practice. I would like to relate some pertinent experiences, at the same time tracing the development of the outpatient department teaching of neurology and psychiatry in Syracuse.

If my memory serves me correctly there was no separate clinic for neurology and psychiatry in my student days. Junior students took histories and did physical examinations in the medical clinic at the Syracuse Free Dispensary, occasionally, of course, seeing a neurologic or psychiatric case. Checking was done by practicing physicians on the dispensary staff. There was a rare opportunity to do a lumbar puncture, under supervision, of course. While an intern, I was afforded an opportunity to work at the Rhode Island Hospital outpatient department in neurology and psychiatry. After internship came alternate days between the Rhode Island Hospital and the Massachusetts General Hospital outpatient departments. Then followed an experience at various clinics as a postgraduate student in neuropsychiatry at the University of Pennsylvania. Here and at the Massachusetts General Hospital there were conferences and a sincere teaching effort, particularly in the clinics of Drs Wm G Spiller, T H Weisenburg, Edward Strecker, and James B Ayer. Then came Syracuse and an opportunity to work at the Syracuse Free Dispensary, which is staffed by the Syracuse University Medical College.

There were two clinics a week in neurology and psychiatry, both types of cases being treated in each clinic. I soon fell into the habit which I had criticized as a student—too much hurry and sacrifice of quality for quantity. I am sure my students of those days would agree that the student had little opportunity to investigate thoroughly and follow up a patient. With the assistance of a well-trained psychiatric social worker, however, an appointment system was worked out and conditions improved substantially. Then in 1931 the Syracuse State Psychopathic Hospital was built and the neuropsychiatric clinic was transferred there. The psychiatric clinic remains there today and I shall speak of that later. Neurology was returned to the Syracuse Free Dispensary where it operates today under the department of internal medicine. I believe that there has been a decided improvement in both clinics, both from the point of view of the clinic physician and from that of the student. The criticisms which your speaker had noted were noted by others. Dr H A Steckel, Director of the Psychopathic Hospital and Professor of Psychiatry, has made many improvements in the teaching done by this department. Dr J G Fred Hiss has reorganized, or shall I say, is reorganizing the work of the department of internal medicine at the Syracuse Free Dispensary with a thought not only to the patient's welfare but also to that of the student and the physician teacher.

Let us consider for a few moments the evolution of the present system of the teaching of neurology in the Syracuse Free Dispensary. Since it became a part of the medical clinic there has been one clinic a week. New cases are first

order to maintain their interest I decided on the plan of having these assistants see the new cases and check with them the following week. At present our new case intake is limited to four per week making two for each assistant. He, of course, follows his cases on an appointment basis.

Let us now discuss the outpatient department teaching in psychiatry. A few years ago Dr. Steckel asked some of us who were specializing in the private practice of psychiatry to take about eight clinics a year in an effort to give the senior students an idea of the extramural practice of psychiatry. There are about five students in each group. My own method is to make appointments for selected cases from my regular clinic at the Psychopathic Hospital and present these cases to the students, considering chiefly diagnosis, prognosis, and treatment. This is followed by a description of the field of extramural psychiatry including psychoses, mental defectiveness, epilepsy and the psychoneuroses, mental hygiene, and child guidance and delinquency. Particular stress is laid upon the psychoneuroses: the patient who after a thorough history and examination is all too often told "You imagine it all—go home and forget it." True, we are not dealing with organic pathology in these cases, but if we consider for a moment the function of the vegetative nervous system, which is very briefly the control of the viscera and circulation and knowing that it is affected by emotions either acute or chronic, can we not explain the bizarre symptomatology presented by these patients? If the student realizes this and later, when he becomes a physician, makes an effort to reach the patient through drugs, endocrines, or particularly an effort to alter the emotional content of the patient's life, we believe that many patients will not turn to cultists. At various times senior and graduate students in psychology and sociology, divinity students, and ministers visit the clinics and, I believe, gain something therefrom. Some act as volunteer assistants in social investigation and psychometric examinations.

A few words about the preparation of the student for the outpatient department work at Syracuse University Medical College: neuroanatomy is studied in the freshman year and neurophysiology the second year. A course in neuropathology is studied along with pathology in the second year, also a course in physical diagnosis. Clinical neurology and clinical neuropathology are taken up in the junior year. Courses in psychiatry are given in the second, third, and fourth years. Bedside work in neurology and psychiatry is considered in the fourth year in clerkships. Each senior makes a thorough study of a case, including home investigation.

I have attempted to give you a word picture of the outpatient department teaching and practice of neurology and psychiatry as I have experienced it. Certain conclusions can be drawn therefrom and suggestions made.

1. There is still much to be desired.

2. Organic neurology should be taught to seniors rather than juniors and the course in physical diagnosis should include the neurologic examination.

3. More time should be allowed so that the student has time for a complete neurologic examination.

4. We do not try to make neurologists out of students but we do expect them to be able to take a good neurologic history, do a good neurologic examination, and interpret it intelligently.

5. There is need for more psychiatric social service investigation.

6. With proper facilities both the neurologic and psychiatric outpatient department can be used to great advantage for the teaching of medical students, for the teaching of physicians who wish to work in the clinic, for postgraduate courses, and also for the teaching of sociology, psychology, and divinity students.

7. Our own outpatient department work in both divisions to a large extent, is in conflict with the oft-heard cry of the medical profession "the patient's choice of physician." But with this situation I have no quarrel as I believe that in the

seen by the ex-medical resident of the University Hospital of the Good Shepherd. Organic neurologic cases are referred to the neurologic clinic. Cases are also referred from the other clinics. At first there were about fifteen junior students working at the clinic. If the neurologist found something of interest such as third, sixth, or seventh nerve involvement, tremor, or clonus he would demonstrate it to the students who worked in groups of two. This then meant that he had to rout out several pairs of students. The result was like the "clam chowder through which the clams walked with rubber boots on." Then a day was set aside for neurology. The students continued to work in pairs. The teacher assigned a case—usually a new one to each group for history and neurologic examination as well as such physical examination as was indicated. The whole group assembled for the last half hour during which one previously selected pair of students presented their case. The professor of internal medicine, under whom the department of neurology maintained their clinic, wanted the students to learn how to write a neurologic history and do a neurologic examination, but I must confess I did not exactly obey orders, for in these half-hour discussions we discussed etiology, pathology, signs and symptoms, differential diagnosis, treatment, and prognosis, even though the students were only juniors. I continue to teach this way because I thoroughly believe the student's interest is better maintained. This plan, bad as it was, was a dawning of a better day. Its faults were obvious. In addition to running the clinic I had to check each pair of students and their case, select the case to be presented, and then discuss the chosen case—all in a period of two hours. Just before this, Dr Hiss had been given charge of the medical clinic. Larger quarters were obtained and I was given carte blanche as far as the neurologic clinic was concerned. One of my colleagues in neuropsychiatry agreed to help, so while one of us had the teaching clinic the other was in charge of the regular

clinic. An appointment basis for patients was arranged. Old cases were used for teaching rather than new ones. My colleague believes in the method of assigning several cases each day. The students are juniors and work in groups of two, the entire group now not exceeding ten. The speaker presents one case to the entire group—one pair of students being responsible for the history and examination which are taken and made in the presence of the physician and the rest of the group. Anyone can interrupt at any time. The last forty-five minutes are reserved for presentation. The professor of neurology holds us responsible for the only teaching which that department presents on multiple sclerosis, syphilis of the central nervous system, extrapyramidal syndromes, and vascular lesions of the nervous system. The students consider these cases as new cases except that they are to take a progress note. They also write the prescription which the teacher, of course, must sign. They are told the week previous what the subject for the following week's presentation will be and are expected to read it in their textbook. At the time the case is presented they are given references to literature and newer methods of treatment. The students do the neurologic examination themselves after having been shown how. You cannot learn to play golf by watching the other fellow. They do a fairly complete examination except that there is little time for a complete sensory examination. Objective tests for taste and smell are not always done nor are complete examinations made of the optic and auditory nerves in which they receive instruction in their senior year. The first session of each group is devoted to a review of neuroanatomy and physiology as applied to the neurologic examination.

Soon after the neurologic clinic became a part of the medical clinic another phase of teaching entered the situation. There were physicians working in the medical clinic who desired to work in neurology. These men serve as assistants. At first they saw the old chronic cases but in

in a special section of this New York State Medical Society Meeting

Dr Harry A. Steckel, *Syracuse, New York*—May I first be permitted to congratulate Dr Chambers upon the interesting and comprehensive manner in which he has covered his subject.

I wholeheartedly agree with everything he has said.

It seems to me he has struck an important keynote in our education program when he emphasizes the value of "quality over quantity." There is no question in my mind but that a few cases studied and discussed in a thoroughgoing manner gets far better results than does a superficial review of a large number.

The time element, however, is always an important factor and with an already overcrowded curriculum it is often difficult to cover the ground satisfactorily.

So far as psychiatry is concerned, the situation at Syracuse has been met this past year. We now complete our didactic instruction in the second year so that more time will be available for case contact for the third-year classes.

Dr Chambers' recommendation that more social service investigation be made possible in our psychiatric teaching program will be followed out with the small clinical groups of third-year students beginning in the 1939-1940 school session and students will be required to make more and better personality and environmental studies than has heretofore been possible.

In closing, I should like to record my appreciation for the excellent support the neurologists and psychiatrists in private practice in Syracuse have afforded us in our teaching program, and to express my hope that the same cordial relationship which we have enjoyed in the past may continue unabated in the future.

SICKLE SWISHES A BIT FASTER

A little higher death rate in 1939 for the United States than in 1938 is forecast in provisional figures for the first six months of 1939 given in *Public Health Reports* (Washington), but we are assured that although the death rate from all causes, 11.2 per 1,000 estimated population, for the first 6 months of 1939 was 2.8 per cent higher than the corresponding rate, 10.9, for 1938, the health of the nation, in so far as it is measured by mortality rates, has been well above the average of immediately preceding years. Some increase in the death rate compared with that for 1938 was to be expected, since the lowest rate in the history of the death registration area was recorded in 1938. The mortality rate from all causes during the current half year is 6 per cent less than the corresponding rate for 1937.

The cause of death with the largest numerical increase was heart disease, which accounted for 8 per cent more deaths than in the previous year. Influenza with an increase of 65 per cent over the first 6 months of 1938, registered the largest relative increase. However, the influenza death rate for the first 6 months of 1938 14.5 per 100,-

000 population, was unusually low, so that the rate for 1939, 23.9 per 100,000 population, was still low when compared with the average of preceding years and, indeed, was only slightly more than one-half the rate for 1937.

Decreases of varying magnitude were reported for the other causes of death. The death rate from the principal communicable diseases of childhood, measles, diphtheria, scarlet fever, and whooping cough, was appreciably less than for 1938. Especially gratifying were the continued declines in the mortality rates from tuberculosis and diseases of pregnancy and childbirth. The death rate from tuberculosis, 47.3 per 100,000 population, decreased 3 per cent and will apparently be definitely below 50 per 100,000 population at the end of the year. The maternal mortality rate reached a new low of 4 per 1,000 live births, this represents a decline of 23 per cent since 1937.

The infant-mortality rate registered a drop of 2 per cent and will be less than 50 per 1,000 live births for the first time in the history of the registration area if the present favorable conditions continue until the end of the year.

"QUINTESENSE"

We understand that Dr Allan Roy Dafeo is now advisory editor of *Parents' Magazine*. It is still too early for anyone but Winchell to predict how this will affect the 1940 census—*The Postage Stamp*

A doctor's little daughter, deeply interested in radio, glanced one morning into the office where her father was testing the heart and lungs of a patient. "Getting any new stations, daddy?" she inquired—*Illinois Med Jour*

case of the indigent they are badly needed for teaching material, and that free choice would soon leave our clinics suffering for lack of material

8 The single case method seems preferable in neurology

9 The outpatient department offers the student the nearest approach to office practice—a fact which I realized as a student. No wonder it finds increasing use for teaching purposes

In conclusion, let me say that the best results can be obtained only when a physician likes to teach and enters into it with enthusiasm, and is as faithful to his dispensary work as he is to his private practice

Discussion

Dr J G Fred Hiss, *Syracuse, New York*—As Dr Chambers and I are associated at the dispensary there is naturally no great difference in opinion regarding the methods discussed in his paper. Therefore, I should like to stress a few points that he made or implied in his description

First, I feel that it is absolutely fundamental that the technic of a simple neurologic examination be taught in the physical diagnosis course in the second year. I am afraid that only too often we give students the impression that a complete examination of the body consists of examining the heart and lungs, calling in various specialists to look at the nose and throat, and making a special neurologic examination. In order to impress the students that we are dealing with the body as a whole, I feel that the teacher in physical diagnosis should teach all of these things, leaving only the more advanced examinations to be taught later on in the course by the proper specialists

Secondly, I believe that third-year students should get their introduction into clinical medicine in the hospital rather than in the dispensary or outpatient department. In hospitals, patients usually have well-developed pathology or are suffering from the more acute conditions which are comparatively easy to recognize. Furthermore, the patient is available for a much longer period of time. If the student is somewhat puzzled on his first examination he can read about it at home during the evening and re-examine the patient the next day. This can be repeated any number of times until the case is properly worked up. At the dispensary, on the other hand, we have many patients with early or

obscure pathologic changes. The time is very limited and the case load that must be taken care of is usually very heavy.

In the third year the student is more interested in methods, while diagnosis and differential diagnosis are of secondary importance.

Third-, senior-, or fourth-year students should be assigned to work in the outpatient department because of the reasons stated above. I feel that in general the value of outpatient department teaching has escaped proper evaluation. It is not generally recognized that one can follow essentially the same methods that have been adopted in the teaching of physiologic, pharmacologic, pathologic, and the other basic sciences, namely, that the material can be arranged in a logical and correlated order.

For examination in pathology, students are assigned a lesion dealing with nephritis. They have a lecture on nephritis, they see gross specimens illustrating types of nephritis, and then they study microscopic sections illustrating the various types of nephritis. If the professor classifies his material in an outpatient department, it is possible to assign a definite subject for students to read and then show them cases illustrating this same subject. One can, for instance, assign the subject of cerebral spinal lues and then arrange his appointments so that on the day of discussion he will have several patients illustrating this condition available in the clinic. In this way it is possible to tie up the didactic and the clinical work so that it becomes a very definite and concrete subject to the student, rather than merely another lesson to be studied or another case to be seen.

At present our students are assigned to this type of work for about forty-five days and our aim is to show them the 45 most common or most important types of disease that are encountered in an outpatient department. This, of course, requires careful diagnosis and classification of cases by the physicians who carry the case load of the various clinics. The appointment system is, of course, also essential.

I might say that this does not comprise all of our medical teaching in the dispensary. Students are also assigned, at another time, new cases to work up completely. Both of the types of teaching here mentioned, I believe, are essential to the complete rounding out of the student's medical education. By this arrangement not only do the students benefit greatly, but the advantages are even greater as far as the patients and attending staff are concerned, as all cases must of necessity be more carefully studied. I feel that it is very commendable that a discussion on teaching methods should be included

X-RAY TREATMENT OF INFLAMMATORY CONDITIONS

JOHN RUSSELL CARTY, M D , New York City

SINCE the early days of x-ray therapy there have been occasional reports detailing good results in the treatment of various inflammatory conditions. As a whole, however, until comparatively recently these observations have been isolated and have not attracted much attention. Now the literature has reached such a volume that their significance cannot be overlooked by the radiologist. The literature has been well summarized in many of the recent papers. In this report our aim is to detail our experience in the treatment of inflammatory conditions for the past twelve years. As is the case with any new agent there is usually an uncritical selection of cases, and, of course, under these conditions the results may be disappointing. The method may undeservedly come into disrepute. In addition to a proper selection of cases there are certain details that must be seriously considered if good results are to follow.

The theories regarding the action of the x-rays on infected tissues are many. A lengthy theoretical discussion of them would not be profitable. The theory that postulates a partial leukocytic destruction by the radiation, thus liberating antibacterial substances seems attractive. I seriously doubt if there is a direct action of the radiation upon the bacteria themselves. As one might expect, the more acute the process the more dramatic the result. On the other hand, a long-standing process requires a longer time and more treatment for a favorable resolution. There is often a marked suppuration following x-ray therapy. Wherever possible the pus and debris should be given an exit as soon as possible as it shortens convalescence and diminishes toxicity.

There is a feeling now that the dosage

of x-rays used is an important and even decisive factor, particularly in the acute processes. In my early work in this field I would encounter an occasional case where the x-rays had apparently aggravated the process. In most of these instances the dosage was relatively large. A recent work with rabbits by Tuggle and Angevine has shown that the spread of certain artificially produced infections may be actually facilitated by large doses of x-radiation. This is particularly true with acute infections. With long-standing infection the question of the size of the dose is not so critical. It is my opinion that in most instances the therapy should be administered by the radiologist working in close cooperation with the surgeon. This applies particularly in the more extensive and serious inflammatory lesions such as gas gangrene, carbuncles, otitis media, etc.

Favorable results may be expected in a goodly percentage of selected cases of sinusitis. I do not believe that x-ray therapy will in most instances stop a discharge but it will alleviate pain particularly in those cases where there has been operative interference without relief. There is usually a shrinkage of the mucous membrane about the ostia which permits of drainage. However, the infected mucous membrane may still remain. The shrinkage about the ostia is usually preceded by a preliminary swelling. This swelling may cause an exacerbation of the pain two to twelve hours following treatment. The possibility of this should always be explained to the patient and when it occurs it is generally indicative of an eventual good result.

Excellent results may be obtained in the case of boils with small doses of x-ray. The boil suppurates very rapidly, sometimes in less than twelve hours, saving

the patient a great deal of pain and suffering. If treated early enough suppuration may be avoided.

With carbuncles the toxicity is diminished. This effect is often striking. In one extensive carbuncle of the face the patient became markedly brighter and less toxic two hours after the first treatment. It softens up and may drain spontaneously or be amenable to relatively simple surgery. In my opinion x-ray therapy is a method of choice in carbuncles of the face. If there is a sinus thrombosis the x-ray therapy will not modify the eventual fatal outlook.

Good results have been reported following x-ray therapy for gas gangrene. The disease may be held in check and radical surgical measures may not be needed. If, however, there is an underlying diabetes or arteriosclerosis, the response is poor.

Excellent results may be obtained in the treatment of phlebitis, particularly of the long drawn-out wandering type. Often weeks of tedious convalescence may be avoided. Occasionally, a chronic ulcer due to varicose veins may heal following x-ray therapy. A recurrence later is apt to happen. Best results are seen where there is not an associated arteriosclerosis.

Bursitis responds well, particularly the very acute type. In fact, I believe better than by the use of heat. With this exception, however, we prefer to have heat tried before x-ray. In certain cases puncture and withdrawal of fluid in addition to x-ray may be helpful.

At present there is not sufficient evidence in my opinion to justify any conclusions regarding the x-ray therapy in acute lobar pneumonia. On the other hand, I have had excellent results with certain chronic pneumonias, particularly those in children. Serial radiographs of the chest are made to check the results of treatment. My experience in treating bronchiectasis has not been so good as those expressed by some other observers. Occasionally one may see a gratifying reduction in the amount of sputum. It is very important to keep a close watch on

the blood count as a severe anemia may occur within a few days during therapy, in this condition. One must also be careful not to push the treatment too vigorously for fear of producing pneumonia. However this is contrary to the experience of some others.

The results of x-ray therapy on enlarged inflammatory lymph nodes, particularly in children, are excellent. Many times a quick reduction in size will take place without pus formation. If there is fluctuation before treatment the nodes will break down more rapidly. There is often a marked reduction in the fever and general toxemia. Any focus of infection such as the tonsils should be removed as soon as the infection quiets down.

Excellent results are seen in the x-ray therapy of chronic inflammatory lymph nodes. A much longer time is usually needed before good effects are apparent. This is particularly so where there is an inflammatory mediastinal enlargement secondary to exanthemata, whooping cough, or upper respiratory tract focus of infection. These patients often have a persistent, dry, brassy cough which may last for months and give rise to apprehension. They are usually anemic and do not gain in weight. Parents should be warned concerning the likelihood of exacerbation of symptoms following the first few treatments. It may take as long as four months before a cure is reached.

The x-ray therapy of middle-ear disease has received attention. Some observers state that operation may at times be avoided in the acute type of otitis media and mastoiditis. I have seen a year-old discharge stop following treatment. More evidence is needed here before drawing conclusions.

The x-ray therapy of herpes zoster is very effective and deserves more attention. We treat over the ganglion and often along the nerve distribution of an affected ganglion. The sooner the patient is treated following the onset of the disease the better are the results. Age to a certain extent plays a part in the results. It has been our experience that the younger the patient the better are the

X-RAY TREATMENT OF INFLAMMATORY CONDITIONS

JOHN RUSSELL CARTY, M D, New York City

SINCE the early days of x-ray therapy there have been occasional reports detailing good results in the treatment of various inflammatory conditions. As a whole, however, until comparatively recently these observations have been isolated and have not attracted much attention. Now the literature has reached such a volume that their significance cannot be overlooked by the radiologist. The literature has been well summarized in many of the recent papers. In this report our aim is to detail our experience in the treatment of inflammatory conditions for the past twelve years. As is the case with any new agent there is usually an uncritical selection of cases, and, of course, under these conditions the results may be disappointing. Excellent results may be obtained in the case of boils with small doses of x-ray. The boil suppurates very rapidly, sometimes in less than twelve hours, saving

Dr Arthur F Holding, *Albany, New York*—Dr Carty has covered a large field and has done it well. I have not had an opportunity of reading his paper beforehand, and I may be mistaken, but in enumerating the wonders in therapy that x-ray can accomplish in refractory cases, I wonder if he has protected himself enough by giving sufficient emphasis on the need of using the x-rays only in cases where simpler, less expensive, less dangerous, and less destructive modalities have failed.

As an old family doctor, an ear, nose, and throat specialist, as well as a veteran roentgenologist, I have little sympathy with the all too common modern attitude of "therapeutic nihilism."

We who have devoted our lives to the x-rays must remember that radiology is more a method and technic than it is a specialty—an adjuvant rather than a specific cure. We must avoid being discredited for overenthusiasm.

For instance, in skin lesions it is well to remember the old dictum "skin diseases are divided into three classes—the first, sulfur will cure, the second, salvarsan and mercury will cure, the third, the devil himself cannot cure," and it is in these cases that the x-rays are indicated.

The vast majority of patients with acute sinusitis will quickly respond to colloidal silver with a touch of adrenalin, followed by hot isotonic antiseptic solution douched through the nostrils by suction irrigation, followed by anointing the membrane with oil, and breathing warm

air night and day. It is in the pain and discharge of chronic, refractory sinusitis cases only that x-rays are important curative agents.

In furunculosis, enlarged lymph glands, and chronic eczema I get better results and prefer ultraviolet light first, and only resort to x-rays when the ultraviolet light fails. Never incise a furuncle or carbuncle near any cartilage, especially near the cartilages of the nose or ear. Many an incised furuncle of a nose has been followed by meningitis and death.

In eczema remember success depends largely on excluding the air, cold, and soap and water from the skin no matter what other treatment may be used.

In enlarged lymph glands without sinuses—if they do not get rapidly better or worse (breaking down to point as abscess) after x-ray—surgery gives better results.

In herpes zoster, since I have used anterior pituitary gland extract hypodermatically I have never had to use x-rays for these patients.

In acute mastoiditis I find I need the x-rays in diagnostic dose methods in order to prove that the patients really had mastoiditis because they get well so fast under sulfanilamide. The greatest usefulness for x-rays in mastoiditis is in old chronic running ears that surgery has failed to clear up.

I am merely adding these words of constructive suggestion to Dr Carty's paper in the hope that it will help searchers after truth and save the x-ray specialists from being misunderstood.

TAKEN FROM LETTERS SENT TO EAST ST LOUIS RELIEF OFFICE

My husband has worked one shift for about two months and now he has left me and I ain't had no pay since he has gone or before either.

Please send me my clopment as I have a four months old baby and he is my only support and I need all I can get every day to buy food and to keep him in close.

I am a poor woman and all I have is gone.

Both sides of my parents is very poor and I can't expect anything from them as my mother has been in bed for one year with one doctor and she won't change.

Please send me a wife's form to fill out.

Please send me a letter and tell me if my husband made application for wife and child.

I have already wrote the President and don't hear from you. I will write to Uncle Same and tell him about both of you.

Mrs. has no clothing for a year and has been visited by the clergy regularly.

I can't get no pay. This is my 8th child. What are you going to do about it?

Sir, I am forwarding my marriage certificate and my two children one of whom is a mistake as you can see.

I am writing you to say that my boy was born two years ago and is two years old. When do I get my relief?

I am annoyed to find out you have branded my boy illiterate. Oh! for shame! It is a shame and a dirty like, as I married his father a week before he was born.

In answer to your letter I gave birth to a boy, weighing 10 lbs 1 oz. I hope you're satisfied.

You have changed my little girl to a boy. Does that make any diff?

I have no children as my husband is a truck driver and works day and nite.

In accordance with your instructions I have given birth to twins in enclosed envelope.

—St. Louis Medical Bulletin

results obtained. As is the case with sinusitis there may be an acute exacerbation of the pain after the first two or three treatments. This is a favorable sign but should be explained to the patient. The poorest results are seen in cases where the patient is beyond fifty and where there is pain although the eruption may have disappeared.

There are many technics used in the treatment of infectious conditions. I do not feel that it is of great moment whether medium wave radiation, that is, 130 KVP, or radiation at 200 KVP is used. We do feel, however, that the amount of radiation given per dose and the size of the port used are of vital importance. In treating acute superficial infections one should not use over 100 r per treatment, preferably 50 to 75. All measurements are given in air to the skin. I do not believe that a 20 by 20 port should be used where the intensity is over 75 r. I do not feel that it is a matter of much importance whether the treatment is given daily or every other day. The radiologist should consider each case on its merit.

The question of filtration apparently does not play a decisive role. I have had excellent results using 200 KVP with 1 mm of copper plus 3 mm of aluminum as a filter. In fact I feel that this technic is superior in the case of sinusitis or enlarged mediastinal lymph nodes. The total dosage in acute infectious processes should be guided largely by the clinical reaction, keeping, of course, below an erythema dose. Many times a total dose of 50 to 100 r will resolve a boil. With chronic infections the intensity per dose may be stepped up and the total dose may be run higher. Here also larger fields can be more safely employed. With chronic infections the period between treatments may be extended to as much as a week.

The following technic has been found satisfactory in the treatment of enlarged tracheo-bronchial lymph nodes in children: voltage—200 KVP, target-skin distance—50 cm, filtration—1 mm copper plus 3 mm aluminum. Fifty to 100 r

(measured in air) to the skin are given each treatment depending upon the age and size of the patient. Four treatments will usually suffice but in larger children it may be necessary to give six. They are given at weekly intervals through two ports to the mediastinum, one in front and one in back, one area per treatment.

Wherever possible the application of irritating substances should be avoided. However, I would not withhold the use of x-radiation on this account. With carbuncles of the face, carbolicization may hasten the evacuation of pus and tissue debris.

Conclusions

X-radiation is a powerful effective weapon in the treatment of many infectious conditions. Incautiously used it is capable of doing harm. Certain precautions to be observed are emphasized.

Discussion

Dr Andrew H. Dowdy, Rochester, New York—Dr. Carty has brought to our attention the increasing usefulness of roentgen-ray therapy in the treatment of inflammatory conditions. The mode of action of this type of therapy is not clearly understood. In experienced hands, however, there is no question of its beneficial effect. A partial destruction of the infiltrated leukocytes, especially lymphocytes, seems certain. Desjardins postulates a subsequent release of ferments and antibodies from these disrupted cells. There is a secondary increase in phagocytosis. The work of Warren and Syvertson definitely indicates that bacteria are not destroyed *in vitro* by the direct action of roentgen rays in the therapeutic dosage range. Clinically we have found positive wound cultures for gas bacilli months after the clinical signs and symptoms of the disease have disappeared following roentgen ray treatments.

The essayist's caution regarding dosage is timely. In acute cases small doses are indicated, large doses may be dangerous. Chronicity is no contraindication but the duration of treatment is longer. In chronic cases some degree of local reaction following treatment is a good prognostic sign. Experience plus clinical judgment will determine the size of the dose and the frequency of treatment.

I should like to ask Dr. Carty what his experience has been with pulmonary abscesses and what technic he has found advisable?

Dr Arthur F Holding, *Albany, New York*—Dr Carty has covered a large field and has done it well. I have not had an opportunity of reading his paper beforehand, and I may be mistaken, but in enumerating the wonders in therapy that x-ray can accomplish in refractory cases, I wonder if he has protected himself enough by giving sufficient emphasis on the need of using the x-rays only in cases where simpler, less expensive, less dangerous, and less destructive modalities have failed.

As an old family doctor, an ear, nose, and throat specialist, as well as a veteran roentgenologist, I have little sympathy with the all too common modern attitude of "therapeutic nihilism."

We who have devoted our lives to the x-rays must remember that radiology is more a method and technic than it is a speciality—an adjuvant rather than a specific cure. We must avoid being discredited for overenthusiasm.

For instance, in skin lesions it is well to remember the old dictum "skin diseases are divided into three classes—the first, sulfur will cure, the second, salvarsan and mercury will cure, the third, the devil himself cannot cure," and it is in these cases that the x-rays are indicated.

The vast majority of patients with acute sinusitis will quickly respond to colloidal silver with a touch of adrenalin, followed by hot isotonic antiseptic solution douched through the nostrils by suction irrigation, followed by anointing the membrane with oil, and breathing warm

air night and day. It is in the pain and discharge of chronic, refractory sinusitis cases only that x-rays are important curative agents.

In furunculosis, enlarged lymph glands, and chronic eczema I get better results and prefer ultraviolet light first, and only resort to x-rays when the ultraviolet light fails. Never incise a furuncle or carbuncle near any cartilage, especially near the cartilages of the nose or ear. Many an incised furuncle of a nose has been followed by meningitis and death.

In eczema remember success depends largely on excluding the air, cold, and soap and water from the skin no matter what other treatment may be used.

In enlarged lymph glands without sinuses—if they do not get rapidly better or worse (breaking down to point as abscess) after x-ray—surgery gives better results.

In herpes zoster, since I have used anterior pituitary gland extract hypodermatically I have never had to use x-rays for these patients.

In acute mastoiditis I find I need the x-rays in diagnostic dose methods in order to prove that the patients really had mastoiditis because they get well so fast under sulfanilamide. The greatest usefulness for x-rays in mastoiditis is in old chronic running ears that surgery has failed to clear up.

I am merely adding these words of constructive suggestion to Dr Carty's paper in the hope that it will help searchers after truth and save the x-ray specialists from being misunderstood.

TAKEN FROM LETTERS SENT TO EAST ST LOUIS RELIEF OFFICE

My husband has worked one shift for about two months and now he has left me and I aint had no pay since he has gone or before either.

Please send me my elopment as I have a four months old baby and he is my only support and I need all I can get every day to by food and to keep him in close.

I am a poor woman and all I have is gone.

Both sides of my parents is very poor and I can't expect anything from them as my mother has been in bed for one year with one doctor and she wont change.

Please send me a wifes form to fill out.

Please send me a letter and tell me if my husband made applicaton for wife and child.

I have already wrote the President and dont hear from you. I will write to Uncle Same and tell him about both of you.

Mrs has no clothing for a year and has been visited by the clergy regularly.

I cant get no pay. This is my 8th child. What are you going to do about it?

Sir, I am forwarding my marriage certificate and my two children one of whom is a mistake as you can see.

I am writing you to say that my boy was born two years ago and is two years old. When do I get my relief?

I am annoyed to find out you have branded my boy illiterate. Oh! for shame! It is a shame and a dirty like, as I married his father a week before he was born.

In answer to your letter I gave birth to a boy, weighing 10 lbs 1 oz. I hope youre satisfied.

You have changed my little girl to a boy. Does that make any diff?

I have no children as my husband is a truck driver and works day and nite.

In accordance with your instructions I have given birth to twins in enclosed envelope.

—St. Louis Medical Bulletin

FRACTURES—IN RURAL COMMUNITIES

MAHLON H. ATKINSON, M.D., F.A.C.S., Catskill, New York

WHEN I was invited to read a paper before this body, the subject "Fractures in Rural Communities" was suggested. It was also suggested that perhaps the professional men of the metropolitan district did not realize the difficulties the rural doctors went through in their fracture work.

At first I was at a loss as to what the difference would be in treating fractures in rural districts. It is true that often the rural man cannot obtain all the help and aid that a large institution may offer, but, more to the glory of the rural man, he has learned how to compensate for this.

Fractures in rural communities are just as much an economical problem as they are in the city. In the rural districts, just as in the metropolitan areas, there has been a much greater number of fractures in late years than in past years—due to the advent of the automobile.

The fractures are more violent, there are more open, compound fractures, more comminuted, more fractures of the skull, and much more injury to the nerves, muscles, blood vessels, tendons, and underlying organs.

The rural doctor must treat these fractures or have them treated, with the same purpose that his metropolitan colleague has, namely, to get as perfect a result as possible with as little financial loss to the patient as possible, and here is where the great difference lies between the rural doctor and the man in a large metropolitan medical center.

In the rural district the doctor lives with the patient, and all the patient's relatives and friends. Everybody knows that John Smith has broken his leg and that doctor so-and-so is looking after him. Usually the entire responsibility

is on the doctor's shoulders. Seldom does a patient ask his rural doctor to call consultants. He places himself in his doctor's hands and with a blind, loyal faith, offers no suggestions nor questions his judgment. He simply believes that the doctor will get him out of his trouble. Whatever may be the result of the treatment, the doctor must gaze upon that leg the rest of his days. He will see John Smith perhaps everyday for years and years, and will be facing John Smith's relatives and friends. There is no getting away from it. The doctor, then, knows from the very beginning that it is his responsibility and that he must obtain a good result.

What then is the result? The rural man has prepared himself to depend to a great extent on his own judgment, ability, and ingenuity.

Throughout the rural districts of New York State a gradual change has occurred. It is seldom that one meets the type of doctor so often visualized as the country doctor. Young, energetic, well educated, and exceptionally well-trained men have taken his place. Men who are able to step into any hospital and show an ability and versatility that would enlighten many of our metropolitan colleagues.

There is a much better cooperation between the medical profession, the surgeon, and the layman. Boy Scouts, industrial first-aid teams, etc., have learned the value of proper, immediate splinting, and what is more important, have learned that when it is possible, they should leave the injured person alone until the local doctor arrives on the scene. The fact that so often a doctor is called to the scene in rural districts has been of utmost importance in the aftertreatment of the injured leg, arm, back, etc.

The doctor is able to give the all-important first aid. He takes charge of the situation. He examines the person and determines what has been injured and to what extent. The doctor knows the value of keeping an individual with a fractured back lying prone on the stomach and transporting him that way, even if it is necessary to use a truck. The patient with the fractured back cannot be picked up and crammed, half sitting up, half prone, into the back seat of a car, finishing the damage to the cord. Such is the usual procedure of well-meaning humanitarians in a city where hospitals exist.

I have had one rural physician tell me that he has used shingles, barrel staves, cigar boxes, orange crates, pieces of spare tires, pieces of tin, and other miscellaneous articles to splint a fracture for transportation. But he always splinted it.

Up to three or four years ago the district which I represent was very rural. The nearest hospital was thirty-five miles from my own town and seventy or eighty miles from the mountain districts. In the entire county there were about twenty-five doctors, pretty well-distributed, and the surprising fact is that there were approximately 11 x-ray machines scattered among these doctors, which indicated that the rural man wished to visualize his fractures just as the metropolitan man does.

Now throughout the rural districts of New York a great many hospitals have been erected, small efficient institutions. In my own district we have one of the three "State-aided Hospitals," on which the state pays one half of the building and equipping expense, and one half of any deficit. This hospital has fifty beds.

It serves a county of 20,000 inhabitants and has approximately seventy-five hospitalized fractures a year.

Through gifts, mostly complimentary gifts to the doctors, and through purchases, we have equipped this hospital with the most complete fracture-treating equipment that can be obtained. Certain men especially interested in fracture work frequently attend the clinics in New York City. They follow closely various new methods advanced for the treatment of fractures, listening and observing carefully all the pros and cons of each new method until such method has proved its value and has been accepted. Then they come home and practice it. And I can assure you that seldom has a fracture case left our institution without its being in a very satisfactory condition. At times we require the judgment and skill of experienced men from the metropolitan area, which I am proud to state has always been given us without thought of their ultimate recompense.

As to the methods of treating fractures, we have no set procedures. Hip fractures—some we nail, others we still use the Whitman Spica. Femur fractures on many we do an open reduction, on the others we use traction. Lower leg fractures—we use the McMillan reduction machine with the stuman pins.

As I observe the various clinics and fracture work done in your metropolitan centers I can see very little difference in the methods, course, and aftereffects in your fractures from those of ours in the rural districts.

In fact, if there is any difference at all, I believe it to be that the patient gets just a trifle better break in the hands of the rural physician.

"ONE DROP ON THE PILLOW AT NIGHT"

The oldest drug prescription known is a stone tablet of 3700 B. C. bearing directions for making an inhalant for treating a head cold.

LIFE IS LIKE THAT

An American doctor owns the only automobile left in Changsha, China, but the roads are so cut to pieces that he can't go anywhere.

FRACTURES—IN RURAL COMMUNITIES

MAHLON H. ATKINSON, M D , F A C S , Catskill, New York

WHEN I was invited to read a paper before this body, the subject "Fractures in Rural Communities" was suggested. It was also suggested that perhaps the professional men of the metropolitan district did not realize the difficulties the rural doctors went through in their fracture work.

At first I was at a loss as to what the difference would be in treating fractures in rural districts. It is true that often the rural man cannot obtain all the help and aid that a large institution may offer, but, more to the glory of the rural man, he has learned how to compensate for this.

Fractures in rural communities are just as much an economical problem as they are in the city. In the rural districts, just as in the metropolitan areas, there has been a much greater number of fractures in late years than in past years—due to the advent of the automobile.

The fractures are more violent, there are more open, compound fractures, more comminuted, more fractures of the skull, and much more injury to the nerves, muscles, blood vessels, tendons, and underlying organs.

The rural doctor must treat these fractures or have them treated, with the same purpose that his metropolitan colleague has, namely, to get as perfect a result as possible with as little financial loss to the patient as possible, and here is where the great difference lies between the rural doctor and the man in a large metropolitan medical center.

In the rural district the doctor lives with the patient, and all the patient's relatives and friends. Everybody knows that John Smith has broken his leg and that doctor so-and-so is looking after him. Usually the entire responsibility

is on the doctor's shoulders. Seldom does a patient ask his rural doctor to call consultants. He places himself in his doctor's hands and with a blind, loyal faith, offers no suggestions nor questions his judgment. He simply believes that the doctor will get him out of his trouble. Whatever may be the result of the treatment, the doctor must gaze upon that leg the rest of his days. He will see John Smith perhaps everyday for years and years, and will be facing John Smith's relatives and friends. There is no getting away from it. The doctor, then, knows from the very beginning that it is his responsibility and that he must obtain a good result.

What then is the result? The rural man has prepared himself to depend to a great extent on his own judgment, ability, and ingenuity.

Throughout the rural districts of New York State a gradual change has occurred. It is seldom that one meets the type of doctor so often visualized as the country doctor. Young, energetic, well educated, and exceptionally well-trained men have taken his place. Men who are able to step into any hospital and show an ability and versatility that would enlighten many of our metropolitan colleagues.

There is a much better cooperation between the medical profession, the surgeon, and the layman. Boy Scouts, industrial first-aid teams, etc., have learned the value of proper, immediate splinting, and what is more important, have learned that when it is possible, they should leave the injured person alone until the local doctor arrives on the scene. The fact that so often a doctor is called to the scene in rural districts has been of utmost importance in the aftertreatment of the injured leg, arm, back, etc.

Read on Fracture Day of the New York and Brooklyn Regional Fracture Committee of the American College of Surgeons, February 25, 1938, at Lenox Hill Hospital, New York City

Antepartum eclampsia occurred in 40 patients (63.5 per cent), intrapartum in 12 patients (19 per cent), and postpartum in 11 patients (17.5 per cent). The incidence, as given by Hinselmann, was 26, 53, and 21 per cent, while Stander's figures of 53, 25, and 22 per cent, respectively, are more comparable to our experience.

Fifty-nine of our patients were treated during the antepartum period by private physicians, and 4 by the clinic staff of the hospital. The records of the 4 clinic patients indicated that they attended regularly and received adequate prenatal care. Of the 59 private patients, 17 were under the supervision of obstetricians and may be assumed to have received good prenatal care. The remaining 42 patients were treated by general practitioners. Inquiry showed that the last-mentioned group likewise received adequate prenatal care in almost every instance.

Table 2 lists all the previous medical, surgical, and obstetric conditions which were noted in the case histories of the 63 eclamptic patients.

TABLE 2—PREVIOUS CONDITIONS IN 57 ECLAMPTICS

Condition	No. of Cases
Eclampsia	3
Postpartum convulsions (undetermined cause)	1
Pre-eclampsia	1
Kidney disease	4
Right kidney abscess and operation	1
Hypertensive vascular disease	1
Scarlet fever in childhood	1
Rheumatic arthritis	1
Enlarged thyroid (nontoxic)	1
Two 7-month premature living infants	1
Two-month spontaneous abortion	1
First pregnancy—forceps delivery and still birth	
Second and third pregnancies—cesarean sections and living infants	1
Breech stillbirth	1
Diabetes mellitus (10-year duration)	1

In view of an earlier statement by J. W. Williams that patients recovering from eclampsia develop a relative immunity to the disease, it is of interest to note in Table 2 that there were 3 cases of recurrent eclampsia in the series (4.8 per cent). *Predisposition, not immunity, exists.*

Peckham, too, noted recurrence in 4 per cent of a series of cases, and Hinselmann in a collective review found it to be 1.92 per cent. One of our recurrent

cases had her original seizure two years prior to the present illness. During her first experience she was delivered of a 7-month stillborn infant and during the current illness of an 8-month stillborn infant. The second patient with recurrent eclampsia likewise was delivered of stillborn infants following both convulsive episodes. The third patient had had antepartum eclampsia with her last pregnancy four years ago which terminated in a stillborn infant. In addition, the series includes a fourth patient who gave a history of postpartum convulsions of undetermined cause during a previous pregnancy, and a fifth who suffered from pre-eclampsia in a former pregnancy which terminated in an 8-month stillbirth.

Four patients gave a history of pre-existing kidney disease (6.3 per cent), one of hypertensive vascular disease and the delivery of a 7-month stillborn infant, one of an operation for abscess of the right kidney, and one of scarlet fever and probable postscarlatinal nephritis. From the preponderance of kidney disorders in the anamneses of these patients it seems difficult to believe that from an etiologic standpoint their presence was merely coincidental.

Although we recall no mention in the literature of familial predisposition to eclampsia, it is worth noting also that one patient whose sister had died of eclampsia is included in this study. The patient recovered after delivery of a living infant.

Treatment

In the absence of a known cause specific treatment is impossible. In this institution eclampsia has been treated along conservative lines. A modification of Stroganoff's method is used, wherein morphine, chloral hydrate, and bromides are given with a view to controlling the convulsions. One colonic irrigation is usually given, but repeated irrigations are no longer favorably regarded. Intravenous injections of hypertonic glucose (100 cc. of 50 per cent) and magnesium sulfate solutions (20 cc. of 10 per cent) have been freely used.

A STATISTICAL REVIEW OF ECLAMPSIA

Based on Twelve Years' Experience in Israel Zion Hospital

FREDERICK WEINTRAUB, M D , Brooklyn, New York

(From the Department of Obstetrics and Gynecology)

IN A total of 31,249 pregnant women admitted to the obstetric service of a general hospital from January 1, 1928, to January 1, 1940, eclampsia occurred in 63 patients. This represents an incidence of eclampsia of 1 in 496 or 0.2 per cent, which is less than the lowest figure (0.34 per cent) given by Stander in a collective review. Hinselmann's figures gathered from various sources place the hospital incidence of the disease at 1 in 253.7 patients, or 0.39 per cent. Different writers have found the incidence to range from 0.34 per cent (Reinburg) to 3.44 per cent (Cruikshank). We are unable to offer any satisfactory explanation to account for the unusually low incidence of the disease in this series. Whether prenatal care alone (which is doubtful) or other factors are responsible remains, for the present, an open question.

Eclampsia is universally found to occur more frequently in primiparas. Of the 63 patients in this series, there were 36 primiparas and 27 multiparas. Private cases numbered 59, and service, 4. There was 1 case of twin pregnancy, and this occurred in a multipara. No patient with hydramnios was observed.

During the cold months (from October through March) 39 patients with eclampsia were admitted (61.9 per cent), and during the warm months (from April through September), 24 patients (38.1 per cent). Unsettled and damp weather is usually held to be a provocative factor in increasing the incidence of the disease. The findings herein reported, with some reservations, support this belief. A monthly analysis of this series shows that during the usually damp and unsettled month of April the least number of eclamptic patients was encountered. Dur-

ing the course of 12 consecutive Aprils (1928 through 1939) there was only one such patient. In sharp contrast, however, stands the month of March. During 12 consecutive Marches (1928 through 1939) the maximum monthly incidence occurred (9 cases). Since weather conditions between these two succeeding months are not as greatly different as they are between months more widely separated in the calendar, the frequently mentioned influence of the weather is not borne out, at least with respect to these two months. Harrar, on the contrary, in a ten-year review of eclampsia in New York City, found April to be the month of greatest incidence of the disease, and, since climatic conditions in New York City and Brooklyn are essentially the same, an other discrepancy appears for consideration. It is apparent, therefore, that further study is necessary before the exact etiologic influence of the weather in relation to eclampsia can be determined.

TABLE 1 — MONTHLY INCIDENCE OF ECLAMPSIA

January 1928 to January 1940							
Month	Jan	Feb	Mar	Apr	May	June	
No. of Cases	5	7	9	1	7	6	
Month	July	Aug	Sept.	Oct	Nov	Dec.	
No. of Cases	3	2	6	8	6	4	

The youngest patient in this series was 21, and the oldest, 45 years of age. Between ages 21 and 30, there were 45 patients (71.4 per cent), between 31 and 40, there were 15 patients (23.8 per cent), and over 40, there were 3 patients (4.8 per cent).

Forty patients developed eclampsia in the ninth month (63.5 per cent), 10 patients in the eighth month (15.9 per cent), 10 patients in the seventh month (15.9 per cent), and 3 patients in the sixth month (4.7 per cent).

TABLE 4 —MATERNAL MORTALITY OF 63 ECLAMPTICS

Cause	Day	Type	Parity	Age	Procedure
Lobar pneumonia	6th postoperative	Antepartum	Primipara	30	Cesarean
Eclampsia	12 hours after admission	Antepartum	Multipara	29	Undelivered
Lobar pneumonia	3rd postpartum	Antepartum	Primipara	24	Spontaneous
Eclampsia	18th postpartum	Antepartum	Primipara	25	Induction spontaneous
Eclampsia	5th postpartum	Intrapartum	Primipara	22	Low forceps
Eclampsia	6th after admission	Antepartum	Multipara	35	Induction spontaneous
Eclampsia	6th after admission	Antepartum	Primipara	27	Induction-spontaneous
Acute cardiac dilatation	3rd after admission	Antepartum	Multipara	39	Attempted induction-undelivered
Eclampsia	3rd after admission	Antepartum	Primipara	24	Undelivered

with intrapartum convulsions, 1 died (8.3 per cent). No deaths occurred in the group of 11 patients with postpartum convulsions (0 per cent).

Under the age of 30 there were 45 patients of whom 6 died (13.3 per cent). In the age group over 30 there were 3 deaths in a total of 18 patients (16.6 per cent).

In the group of 36 primiparas, 6 fatalities occurred (16.6 per cent), and in the multiparous group of 27 there were 3 fatalities (11.1 per cent).

Primiparity and age, therefore, were apparently factors in increasing the mortality in this series. The primiparous labor, being longer and more strenuous, not only exacts greater physical toll from an already embarrassed myocardium but also prolongs the period of subjection of the patient to the action of the eclamptic poison—an action which usually abates rapidly after delivery. The correlation between the older age group and the higher mortality rate is perhaps explicable on the basis that pre-existing hypertensive and kidney disease is likely to be more advanced in that group.

There were 21 stillborn infants, giving a mortality rate of 33.3 per cent. One infant died seven days after delivery.

Summary

1 In a total of 31,249 pregnant women admitted to the obstetric service of a general hospital from January 1, 1928, to January 1, 1940, eclampsia occurred in 63 patients, or 1 in 496 (0.2 per cent). Others report an incidence ranging from 0.34 to 3.44 per cent.

2 Of the 63 patients, 36 were primiparas, and 27 multiparas. There was 1 case of twin pregnancy, and none of hydramnios.

3 During the cold months (from October through March) 39 patients with eclampsia were admitted (61.9 per cent). During the warm months (from April through September) 24 patients were admitted (38.1 per cent). April was the month of minimum, and March of maximum incidence of the disease. The monthly incidence is tabulated and discussed, and certain discrepancies with respect to the etiologic influence of the weather are considered.

4 The youngest patient in the series was 21, and the oldest 45 years of age. Between 21 and 30, there were 45 patients (71.4 per cent), between 31 and 40, there were 15 patients (23.8 per cent), and over 40, 3 patients (4.8 per cent).

5 In the ninth month there were 40 patients (63.5 per cent), in the eighth month there were 10 patients (15.9 per cent), in the seventh also 10 patients (15.9 per cent), and in the sixth, 3 patients (4.7 per cent).

6 The series included 3 cases of recurrent eclampsia (4.8 per cent). The general conception of immunity results in a hazardous sense of security. *Predisposition, not immunity, exists.*

7 Previous medical, surgical, and obstetric conditions which were noted in the case histories of the 63 patients are enumerated and discussed. From the preponderance of kidney disorders in the anamneses it appears unlikely that from an etiologic standpoint their presence was coincidental.

8 The treatment given was a modification of Stroganoff's method. Morphine, chloral hydrate, bromides, intravenous injections of hypertonic glucose and magnesium sulfate solutions were freely used.

9 Failure to respond to therapy after

In those cases in which the response to therapy was unfavorable, labor was induced after a period of close observation which varied, in individual cases, from twenty-four hours to three or more days. The improvement often observed in the general condition of some patients only after several days of the above-mentioned therapy has called into question the soundness of routine induction of labor in cases which have been under treatment for only twelve to twenty-four hours. A longer period will commonly effect better sedation and dehydration as well as improvement in the hepatic and vascular functions.

Both in the primipara and multipara induction, when indicated, was accomplished by rupture of the membranes and insertion of a bag in the uterus. Occasionally (3 cases), in the primipara with alarming symptoms and the prospect of a long labor, abdominal delivery was undertaken. One multipara was subjected to cesarean section for cephalopelvic disproportion. The results and other details relative to induction of labor and cesarean section appear below.

This hospital has been in existence only since 1922, a time when the conservative plan of treatment of eclampsia had already been widely adopted. Therefore, we have no statistics bearing on the radical treatment in vogue before this period.

Induction of Labor

Of the 63 cases in the series, surgical induction of labor was done in 19 (30 per cent). Rupture of the membranes and insertion of a hydrostatic bag in the uterus were done in 17 patients, and in 2 patients a rectal tube was used in place of the bag. Fifteen of the 19 patients delivered spontaneously of whom 12 recovered (80 per cent), and 3 died (20 per cent). The remaining 4 patients were delivered by forceps, and all recovered (100 per cent).

There was a case in which labor was medically induced by means of castor oil, quinine, and enema. Spontaneous delivery and recovery ensued.

TABLE 3—METHODS OF DELIVERY OF 63 ECLAMPTICS AND RESULTS

Method	No of Cases	No of Deaths
Spontaneous	39 (61.9%)	4 (10.3%)
Forceps	16 (25.4%)	1 (6.6%)
Cesarean section	4 (6.3%)	1 (25%)
Breech extraction	1 (1.6%)	1 (100%)
Undelivered	3 (4.8%)	3 (100%)

Mortality

In the group of spontaneous deliveries (shown in Table 3) are included the 10 patients, previously referred to, in whom labor was induced. There were in the induced group, as has been stated, 3 fatalities (20 per cent) which is considerably higher than in the group of spontaneous deliveries in which induction of labor was not done. The latter group consists of 24 patients of whom 23 recovered and 1 died (4.2 per cent). The difference in mortality rates between the two groups is probably due to the fact that induction of labor was resorted to in the more severe and refractory type of case. Three of the cesarean sections were done in primiparas, of whom 1 died. One was done in a multipara who recovered. Of the 3 patients who died undelivered, 1 was a multipara in the ninth month with a fulminating toxemia which terminated her life twelve hours after admission, another, also a multipara, was subjected to an attempt at bag induction of labor for severe eclampsia which, however, was ineffectual. She died of acute cardiac dilatation three days after admission. The third patient was a primipara who died 3 days after admission. No attempt at induction had been made.

There were 9 deaths in the 63 cases, a mortality rate of 14.3 per cent. In 6 cases, eclampsia was given as the cause, in 2, lobar pneumonia, and in 1, acute cardiac dilatation. Eden in an analysis in Great Britain reported a maternal mortality rate of 22.5 per cent. Teel and Reid, of Boston, found an uncorrected mortality rate of 26.6 per cent which is close to the average of 20 to 25 per cent generally reported.

In the group of 40 patients whose convulsions began antepartum, there were 8 deaths (20 per cent). Of the 12 patients

THE VALUE OF BLOOD SEDIMENTATION RATE IN INTRACRANIAL TUMORS

WALTER O KLINGMAN, M D , ROBERT W LAIDLAW, M D ,
and HYMAN SPOTNITZ, M D , New York City

THE blood sedimentation rate, a valuable laboratory aid in clinical medicine, has not been widely investigated or used in clinical neurology. Perhaps the chief reason for this is that the blood sedimentation rate is increased in many general diseases and occasionally gives inconsistent results. We became interested in its possible value in neurologic disorders particularly because of the difficulty in differentiating between various types of brain tumor.

A study, therefore, was undertaken by obtaining the blood sedimentation rates in 679 cases admitted to a general neurologic service. This particular report is limited to the findings we obtained in 125 cases of verified intracranial tumors and in 43 cases of psychoneurosis used for a control group.

Previous attempts to utilize the blood sedimentation rate in the diagnosis of nervous diseases have been made. Biernecki in 1897 became interested in the sedimentation rate but no extensive investigation was made by him. Grün noted that in tumors of the nervous system normal and increased sedimentation rates were found and that no apparent relationship between the malignant character of a lesion and the blood sedimentation rate existed. He did feel, however, that degeneration of tumors caused an increase of the blood sedimentation rate. Others such as Runge, Demetre and Tonuvici made studies on many conditions in the nervous system but came to no helpful conclusions from their findings. Our findings confirm more or less those already made by Abrahamson and Ask-Upmark in regard to intracranial tumors.

The present series of cases of intracranial tumors, proved either by operation or by autopsy, were all cases with clinical signs. Care was taken to eliminate from consideration all cases in which there was elevation of body temperature, anemia, or complications outside of the nervous system. All of the cases were examined by medical consultants. No attempt was made to determine the total plasma, protein, albumin, globulin, fibrinogen, globulin fractions, and euglobulin in these cases. The Westergren method was used and no correction for cell volumes was made.

The accompanying charts record our findings more graphically than one can describe them. As a control group we selected a series of 43 cases where a diagnosis of psychoneurosis was made. The average sedimentation rate for this group was 6.6 mm in one hour, this rate falling within the limits of normal for the Westergren method in which 10 mm is considered to be the upper limit of normal. The cases of intracranial tumor studied numbered 125. Of these there were the following groups:

	Cases
Astrocytoma	26
Meningioma	30
Glioblastoma Multiforme	35
Chronic Subdural Hematoma	11
Metastatic Malignant Tumors	23

Other types of brain tumors were included in our study but the number in each group was insufficient. Particularly only 4 instances of brain abscess were encountered and the sedimentation rate was elevated in only one case and that elevation was very moderate.

an interval of one to three days, depending on individual circumstances, was regarded as an indication for induction of labor. A period of twelve to twenty-four hours was usually considered insufficient to determine indication for induction.

10 Rupture of the membranes and insertion of a bag in the uterus was the method used for induction of labor in most cases.

11 Of the 63 cases, surgical induction of labor was done in 19 (30 per cent). Three of the patients died (15.8 per cent).

12 Of the 63 cases, 39 were delivered spontaneously with mortality rate of 10.3 per cent, 16 by forceps with mortality rate of 6.6 per cent, 1 breech extraction with recovery, and 3 died undelivered. Four patients were delivered by cesarean section of whom 1 died—a mortality rate of 25 per cent.

13 Nine deaths occurred in the 63 cases (14.3 per cent). The mortality rates for ante-, intra-, and postpartum eclampsia were 20, 8.3, and 0 per cent, respectively. For patients under the age of 30, the mortality rate was 13.3 per cent, and for those over 30, it was 16.6 per cent. The mortality rate in primiparas was 16.6 per cent, and in

multiparas, 11.1 per cent. Reasons for the higher mortality rate in the elderly primiparous group are suggested. A mortality table is presented.

14 The infant mortality rate was 33.3 per cent.

Grateful acknowledgement is here made to Dr. Leo S. Schwartz, chief of staff, for his valuable cooperation in the composition of this report, and to all staff members whose private case records have been utilized. To Messrs. H. Merenstein and H. Levy particular credit is due for laborious assembling from the case records of the essential data which form the basis of this review.

THE PHYSICIAN'S LOT CAN BE A HAPPY ONE

(With apologies to W. S. Gilbert's "The Policeman's Lot Is Not A Happy One.")

When the average woman patient isn't ailing—
 Isn't ailing,
 She's a most unhappy person, to be sure—
 To be sure,
 For she certainly believes her health is failing—
 Health is failing,
 And calls upon the doctor for a cure—
 For a cure
 Perhaps he finds she's to become a mother—
 -Come a mother,

Then she begs him to deliver her a son—
 Her a son,
 Ah, take one consideration with another—
 With another,
 The physician's lot can be a happy one—
 Happy one!
 O when ob-stet-ric'-al duty's to be done—
 To be done,
 The physician's lot can be a happy one.
 L. R. D.

as well as general medical conditions. The sedimentation rate is of aid in differential diagnosis and should be considered just as important as the pulse rate, body temperature, spinal fluid findings, blood count, or other laboratory tests.

Summary and Conclusions

The sedimentation rate in a series of 125 cases of verified intracranial tumors was studied and compared with the sedimentation rate in a series of patients clinically considered to be psychoneurotics. It was found that in both types of

The average sedimentation rates for *all* cases in these groups were found to be as follows

In One Hour

	<i>Mm</i>
Astrocytoma	8 7
Meningioma	14 5
Glioblastoma Multiforme	17 8
Chronic Subdural Hematoma	28 2
Metastatic Malignant Tumors	29 5

When one takes only the cases in each group with increased sedimentation rates above 10 mm in one hour, we have the following averages

In One Hour

	<i>Mm</i>
Psychoneurosis	15 1
Astrocytoma	17 6
Meningioma	20 5
Glioblastoma Multiforme	26 8
Chronic Subdural Hematoma	33 1
Metastatic Malignant Tumors	34 6

Table 1 gives a listing of the sedimentation rate made in each case in every group, the crosses indicating rates considered in the normal range of 0 to 10 mm in one hour. The solid squares indicate the cases in each group with a rate above 10 mm.

Table 2 shows a comparison of the average increase in the sedimentation rates above 10 mm in each group.

Table 3 shows the percentage of cases having increased sedimentation rates in each group.

Discussion

As may be seen from the above report, despite the fact that all the types of tumors occasionally had normal values, the sedimentation rate tends to show both an absolute increase in value and an increase in the frequency of an elevated sedimentation rate, as the type of tumor becomes more malignant. It is evident from the results of the above study that the metastatic malignant tumors have the highest sedimentation rates and the greatest frequency of an abnormal sedimentation rate. This finding is not surprising and is in harmony with present-day conception of the relation of the in-

creased sedimentation rate to absorption of toxins and other products of tumor metabolism. It appears fairly definite that the primary brain tumor, glioblastoma multiforme, produces quite frequently an elevated sedimentation rate and our figures indicate that the sedimentation rates associated with this type of tumor are similar to those found in patients with metastatic growths. Clinically, the true glioblastoma multiforme is the most malignant of the primary brain tumors.

In general these studies appear to indicate the trend that the more malignant the tumor, the more likely the sedimentation rate is to be elevated and the higher the rate is likely to be. There is one important exception to this generalization. It is noteworthy that the subdural hematoma cases revealed a sedimentation rate of a type similar to that observed in the cases of metastatic malignant tumors.

This finding may eventually be of considerable significance and of help in arriving at a diagnosis of intracranial hemorrhage and organizing hemorrhage following head injury. Further studies are being pursued by us at this time in all cases of head injury.

Another interesting finding is that meningioma tended to have higher sedimentation rates than astrocytoma whereas clinically the meningiomas are the most benign of all the intracranial tumors. It is difficult to explain this reversal and if substantiated by further study raises the question whether meningioma produces more toxic products than astrocytoma but because of its relative accessibility and position gives a better prognosis.

From these studies it can be considered that the blood sedimentation test is fundamentally nonspecific and its real function should be to indicate presence of disease. A normal sedimentation rate does not mean that the patient has no disease, but when the sedimentation rate is found to be increased one can be certain that some abnormality exists. This holds true for neurologic conditions.

TABLE I

as well as general medical conditions The sedimentation rate is of aid in differential diagnosis and should be considered just as important as the pulse rate, body temperature, spinal fluid findings, blood count, or other laboratory tests

Summary and Conclusions

The sedimentation rate in a series of 125 cases of verified intracranial tumors was studied and compared with the sedimentation rate in a series of patients clinically considered to be psychoneurotics It was found that in both types of

TABLE II

patients the sedimentation rates might be normal or elevated. The frequency of an elevated sedimentation rate was greater in patients with intracranial tumors and the greater frequency of elevated rates was found in those patients with the more malignant tumors. Also, the more malignant tumors tended to give the highest values in the sedimentation rates.

The relatively high value and the comparative frequency of elevated sedimentation rates in patients with subdural hematoma suggest that an elevated sedimentation rate in patients with head injuries may be of value in the diagnosis of intracranial hemorrhage and production of chronic subdural hematoma.

A normal sedimentation rate in a patient suspected of having an intracranial tumor does not rule out the possibility that such a tumor may be present. The more elevated the sedimentation rate is, the more likely is the tumor to be comparatively malignant.

The intracranial tumors listed in the order of their tendency to produce abnormal sedimentation rates are (1) metastatic malignant tumor, (2) subdural hematoma, (3) glioblastoma multiforme, (4) meningioma, (5) astrocytoma.

No relationship could be found between the elevation of the sedimentation rate

and the spinal fluid pressure, spinal fluid protein and cells in patients with intracranial tumor.

Discussion

Dr. Leon H. Cornwall, New York City—Dr. Klingman's figures for sedimentation rates in intracranial neoplasms represent, in my opinion, a correct evaluation of the subject and his conclusions are in accord with those of others who have investigated the sedimentation speed in cerebral disorders.

It is somewhat interesting that Singer and Edel, two foreign investigators, reported two years ago on a group of neurologic cases that was numerically almost identical with Dr. Klingman's group of intracranial neoplasms. The number of neoplasms in their series was of course much smaller than that covered by Dr. Klingman's report.

Singer and Edel reported normal sedimentation rates for hydrocephalus and serous meningitis, slightly increased rates in cerebral tumors, moderately increased rates in subdural hematomata, and greatly increased rates in acute encephalitis and metastatic carcinoma.

The frequent occurrence of elevated sedimentation rates and of relatively high values in glioblastoma multiforme, subdural hematomata, and metastatic neoplasms, is due, in my opinion, to the factors suggested by Dr. Klingman, viz. products of tissue destruction. Of the intra

cranial tumors there is usually more tissue destruction in glioblastomata and metastatic tumors than in astrocytomata and meningiomata, and it seems to me that this offers a satisfactory explanation. I dare say that a quantitative determination of the lipid content and of the various protein fractions in the cerebrospinal fluid might throw some more light on the biochemical mechanisms concerned.

The high values in subdural hematomata do seem puzzling at first thought, but I would be inclined to regard this as due to the destruction of tissue that results from pressure on the subjacent brain tissue. The cases that were available for investigation were of course in the hospital because of clinical symptoms and the symptoms were induced by the pressure effects of the hematomata.

It is not easy to explain the absence of similar findings in meningiomata, however, because these neoplasms often attain large size and produce widespread degeneration of neural tissue. The degenerative process probably occurs much more gradually in the case of meningiomata, and this may be the explanation for the lower rates than in the case of subdural hematomata.

Recently I have reviewed the sedimentation rates in 54 cases of neurosyphilis and found them above 10 mm per hour in 32, or 60 per cent. The average values in these 32 cases was 30.5 mm or slightly under Dr. Klingman's figures for subdural hematoma and metastatic neoplasia.

Dr. John S. Lawrence, Rochester, New York—It has been a pleasure to listen to this presentation by Dr. Klingman. I feel that he and his associates are to be commended for presenting data which will incite others to use the sedimentation of the red blood cells in the study of neurologic disorders. Their findings, as pointed out by them, are in conformity with what is known about the sedimentation rate in other conditions. It is well known that malignant lesions with metastases are prone to be associated with rapid sedimentation rates. This is not a specific reaction in any sense of the word but is probably related to tissue degeneration and destruction. This probably explains the fact that these authors have found high values in subdural hematomata. I am skeptical as to how much

reliance can be placed on this test as an aid in differential diagnosis in neurologic disorders, for it has been found in most other conditions to be much more useful as an aid in studying the course of an established disease than in actually making the diagnosis. However, the data which have been presented, are suggestive and certainly warrant further trial. Inasmuch as metastatic brain tumors are associated usually with more tissue destruction than other brain tumors, they should, *other things being equal*, show a sedimentation rate greater than that found in other brain tumors, but the method can, at best, only be used as an additional laboratory aid in establishing a diagnosis and that is just what the authors contend.

I would like to ask Dr. Klingman if he included nausea and vomiting with dehydration in the statement "complications outside of the nervous system." Many patients with subdural hemorrhage and metastatic brain tumor present these symptoms, which would, I believe, affect the sedimentation rate.

Further, I think it of some importance to know the distribution of the cases between male and female. One would expect somewhat higher values normally for women than for men.

Dr. Klingman stated that cases with "anemia" were excluded. This would make the values reported more reliable, as sedimentation rates obtained by a single reading at the end of an hour are likely to be unreliable in the presence of anemia due to the rapid packing period. This presents a definite limitation for use of this method in brain tumors since it has been our experience that an appreciable number of these patients has anemia. Of course the method can be modified to correct this, but Cutler, Park, and Herr have recently shown that the correction ordinarily used is incorrect and that readings at the end of one hour cannot be used in making an accurate allowance for anemia.

I wish the authors had found it possible to make observations on the fibrinogen and globulin values as I feel one or both of these substances would, most probably, be altered in those conditions associated with rapid sedimentation rates.

This is a provocative paper and one that will do much good by making us think of the sedimentation rate in neurologic disorders.

This presents a definite limitation for use of this method in brain tumors since it has been our experience that an appreciable number of these patients has anemia. Of course the method can be modified to correct this, but Cutler, Park, and Herr have recently shown that the correction ordinarily used is incorrect and that readings at the end of one hour cannot be used in making an accurate allowance for anemia.

I wish the authors had found it possible to make observations on the fibrinogen and globulin values as I feel one or both of these substances would, most probably, be altered in those conditions associated with rapid sedimentation rates.

This is a provocative paper and one that will do much good by making us think of the sedimentation rate in neurologic disorders.

Of all allergies the commonest is a sensitivity to situations, both social and psychic.—*Fetterman*

"It's better to have halitosis than no breath at all."—*Credited by the Medical World to Confucius, who is not in a position to repudiate it.*

TABLE II

patients the sedimentation rates might be normal or elevated. The frequency of an elevated sedimentation rate was greater in patients with intracranial tumors and the greater frequency of elevated rates was found in those patients with the more malignant tumors. Also, the more malignant tumors tended to give the highest values in the sedimentation rates.

The relatively high value and the comparative frequency of elevated sedimentation rates in patients with subdural hematoma suggest that an elevated sedimentation rate in patients with head injuries may be of value in the diagnosis of intracranial hemorrhage and production of chronic subdural hematoma.

A normal sedimentation rate in a patient suspected of having an intracranial tumor does not rule out the possibility that such a tumor may be present. The more elevated the sedimentation rate is, the more likely is the tumor to be comparatively malignant.

The intracranial tumors listed in the order of their tendency to produce abnormal sedimentation rates are (1) metastatic malignant tumor, (2) subdural hematoma, (3) glioblastoma multiforme, (4) meningioma, (5) astrocytoma.

No relationship could be found between the elevation of the sedimentation rate

and the spinal fluid pressure, spinal fluid protein and cells in patients with intracranial tumor.

Discussion

Dr Leon H. Cornwall, *New York City*—Dr Klingman's figures for sedimentation rates in intracranial neoplasms represent, in my opinion, a correct evaluation of the subject and his conclusions are in accord with those of others who have investigated the sedimentation speed in cerebral disorders.

It is somewhat interesting that Singer and Edel, two foreign investigators, reported two years ago on a group of neurologic cases that was numerically almost identical with Dr Klingman's group of intracranial neoplasms. The number of neoplasms in their series was of course much smaller than that covered by Dr Klingman's report.

Singer and Edel reported normal sedimentation rates for hydrocephalus and serous meningitis, slightly increased rates in cerebral tumors, moderately increased rates in subdural hematomata, and greatly increased rates in acute encephalitis and metastatic carcinoma.

The frequent occurrence of elevated sedimentation rates and of relatively high values in glioblastoma multiforme, subdural hematomata, and metastatic neoplasms, is due, in my opinion, to the factors suggested by Dr Klingman, viz products of tissue destruction. Of the intra-

TABLE I

Apparent Cure Rate and Duration of Disease
(219 Male Cases)

Days Duration before Treatment	Percentage of Apparent Cure	Number of Cases
1-7	65.9	44

11-14	90.9	22
15-20	81.6	38
21-27	100.0	27
28 and over	96.7	60

this procedure was repeated on from two to more than six occasions before discharging the patient from the hospital

A few patients, apparently cured, as judged by smear and clinical examinations, were classified as failures solely on the basis of gonococci-positive cultures from prostatic secretions

In female patients, following the cessation of clinical evidence, repeated smears and cultures were made from specimens of exudates expressed from the urethra and cervix. In all cases these examinations extended over one or more menstrual cycles. The persistence, in a few patients, of a slight amount of chronic endocervicitis after repeated negative findings by smear and cultural methods was considered to be nongonorrheal. This is in agreement with the conclusion of Bourne² and Meigs³ from their work in chronic endocervicitis

Results

Following the above routine, apparent cures were recorded in 115 of the group of 123 female patients, a cure rate of 95.1 per cent. The average post-treatment period of observation was seventy-three days and an average of six culture studies was carried out. In the cases complicated by pelvic inflammation there was

marked subjective improvement following response to the therapy with a more or less rapid disappearance, or marked diminution in the size of palpable masses. In several cases, however, pelvic masses persisted. Two cases of mild gonococcal arthritis responded promptly to the therapy. Of the 8 cases which were classed as therapeutic failures, the duration of the infection was under twenty days in 2 instances and of a longer time than this in the remaining 6.

In the 219 cases of male infection a general cure rate of 84.9 per cent was obtained. In the successful cases there were prompt amelioration of symptoms and rapid improvement in those cases exhibiting acute posterior urethritis, prostatitis, epididymitis, vesiculitis, and acute arthritis. There was a less prompt response in instances of chronic articular involvement. In only 1 case was an extension of the infection observed during the therapy. An average of three culture studies was carried out as criteria of cure.

Optimal Time of Treatment as Regards Duration of Infection

In the material under scrutiny the duration of the obvious infection prior to the employment of sulfanilamide therapy apparently plays an important role in

FURTHER OBSERVATIONS IN SULFANILAMIDE THERAPY OF GONOCOCCAL INFECTIONS

C J VAN SLYKE, M D, and J F MAHONEY, M D, Staten Island, New York
(From the Venereal Disease Research Laboratory, U S Marine Hospital, Staten Island)

AS THE use of sulfanilamide therapy in gonococcal infection passes into the third year of clinical evaluation, it seems to have been proved abundantly that the drug is basically capable of producing a high percentage of clinical and bacteriologic cures. As summed up by Pelouze,¹ the cure rate appears to be highest in series of hospitalized patients and to assume a lower level in groups treated under outpatient and office conditions in which adherence to a strict routine is dependent largely upon the degree of cooperation extended by the patient. In the present paper it is desired to present further data upon general cure rates in hospitalized patients as these rates are influenced by the duration of infection at the time treatment is instituted, to review briefly a few of the hypotheses advanced in explaining the therapeutic action of these compounds, and to record some additional observations upon the dosage and upon the occurrence of serious complications.

Material

The clinical material upon which the bulk of these observations has been made consists of a group of 219 adult males and 123 adult females. In all instances the diagnosis was confirmed by culture methods and not any of the patients had received sulfanilamide treatment prior to the present hospitalization. In addition, the records of 906 cases of male infection, treated and documented by the authors, have been drawn upon for certain supporting data and to give a broader base to the subsequent discussion.

Routine Treatment

Since all of the patients were adults and free from deterring complications, a

vigorous therapy was employed. The usual dose of the drug approximated 0.1 Gm per kilogram of body weight, the maximum dose being 8 Gm per day. The drug was administered at four-hour intervals throughout the twenty-four hours in order to effect and maintain a high and uniform level of blood concentration. Fluid intake was restricted to 1,000 cc per day as an aid to the maintenance of the concentration level. As a rule the daily dosage was reduced to 4 Gm on the third or fourth day and continued in this reduced amount until the eighth day when, in most instances, the drug was discontinued. In only a few patients was the therapy maintained for as long as twelve days. The variations in the daily amount of drug administered became an individual matter dictated by the rapidity of clinical response, the intensity of toxic manifestations, and the presence of temperature elevation. A temperature elevation above 38.2° C was considered a sufficiently important danger sign to warrant an immediate cessation of therapy. Not any local treatment was carried out.

Criteria of Apparent Cure

In cases in which there was not any appreciable evidence of clinical response before the sixth day, the therapy was discontinued and the case classed as a therapeutic failure. In male cases a recession of symptoms, cessation of urethral discharge, clearing of the urine, and disappearance of the gonococcus in smear, were followed by the passage of a middle-sized sound and massage of the penile urethra. Material expressed in this way, as well as the secretion produced by prostatic massage, was studied by smear and culture. In cases of apparent cure

In the 219 cases of male infection a general cure rate of 84.9 per cent was obtained. In the successful cases there were prompt amelioration of symptoms and rapid improvement in those cases exhibiting acute posterior urethritis, prostatitis, epididymitis, vesiculitis, and acute arthritis. There was a less prompt response in instances of chronic articular involvement. In only 1 case was an extension of the infection observed during the therapy. An average of three culture studies was carried out as criteria of cure.

Optimal Time of Treatment as Regards Duration of Infection

In the material under scrutiny the duration of the obvious infection prior to the employment of sulfanilamide therapy apparently plays an important role in

blood did not appear to increase the incidence rate of acute anemia. As mentioned before, the temperatures of the patients of the series under discussion were determined every four hours and sulfanilamide therapy was interrupted or discontinued whenever a temperature rise to more than 38.2°C (100.8°F) occurred. It is not improbable that this precaution has helped to forestall the production of acute anemia in the 1,248 sulfanilamide treated cases of gonorrhea observed by the authors.

Scheckel and Price¹⁶ have reported a collection of 10 fatal cases of granulocytopenia in patients who had been given sulfanilamide for a minimum of fifteen days and an average of twenty-seven days. These workers stated that the quantity and prolonged use of the drug were the significant factors. Again it is stated that, in the 1,248 cases of the authors, sulfanilamide was administered for not more than twelve days and usually for seven to nine days. This avoidance of prolonged administration of sulfanilamide and the cessation of treatment immediately upon the appearance of fever or of a toxic dermatitis is considered to be of importance in explaining the absence of granulocytopenia in this series, although obviously these precautions cannot protect against those cases which may arise due to a specific idiosyncrasy.

Dosage and Concentration

It has again been found, as previously reported,¹¹ that a high blood concentration of sulfanilamide by itself does not effect a cure of the gonococcal infection. However, if consideration was given to the duration of the disease before starting sulfanilamide treatment, better results were usually obtained most readily in those patients who secured and maintained a high concentration of sulfanilamide in the blood during the first few days of treatment. The restriction of fluid intake to 1,000 cc. per day promotes a higher blood concentration of sulfanilamide, in accordance with the findings of Marshall, Emerson, and Cutting⁸ and

Stewart, Rourke, and Allen.⁹ The necessity of limiting fluid intake is, however, not in agreement with the report of Alyea, Daniel, and Yates.¹⁰

It has been the experience of the authors that early—particularly early and inadequate—dosage of sulfanilamide produces a condition resembling a sulfanilamide resistance. A second or third therapeutic attempt with sulfanilamide in an adequate dose results in a high percentage of failures in these cases.

The possibility of a subcurative action of sulfanilamide is not ignored. In the face of our present lack of knowledge concerning the mode of action of sulfanilamide, the necessity of a careful and prolonged period of observation is recognized and urged. Cures should be considered as apparent and not proved. A final discharge should not be granted until re-examinations over a considerable period have failed to reveal any residual gonococcal infection.

Summary

On the basis of accumulated experience, hospitalization of patients with gonococcal infections during the period of sulfanilamide treatment seems to be advantageous. It permits of an intensive form of therapy and provides the safeguards that are apparently useful in forestalling the production of severe toxic manifestations.

Further, it seems evident that the favorable responses to sulfanilamide therapy increase definitely by delaying the institution of treatment for a time sufficiently long to allow the establishment of an immune mechanism in the greatest number of patients. As previously noted, this satisfactory development of an immune mechanism appears accomplished in practically all patients within a period approximating twenty-one days. It is to be regretted that there is at present not any laboratory method capable of detecting or measuring this immunologic factor. A procedure of this kind would be of value in determining the individual optimal time for initiation of sulfanilamide therapy.

Conclusions

In a series of 342 male and female cases of proved and hospitalized gonococcal infection, a general cure rate of 87.4 per cent was obtained with sulfanilamide therapy.

When analyzed in accordance with the duration of infection prior to the inauguration of treatment, the cure rate progressively increases with the duration of obvious disease.

Adopting an arbitrary dividing point of twenty-one days, the cure rate increases from 74.5 per cent in the group treated prior to this time interval to 96.1 per cent in cases in which the disease existed for more than this period.

A co-existing immune mechanism seems to be essential to the prompt chemotherapeutic effect of the drug.

Severe blood dyscrasias were not encountered in a total series of 1,248 cases, due possibly to the short but intensive routine of treatment employed and the consideration given to the degree of febrile response of the patient.

The advisability of delaying sulfanilamide therapy until after the obvious disease has been present for twenty days is suggested.

Discussion

Dr Josephine B Neal, *New York City*—We have at present three chemicals neo-

prontosil, sulfanilamide, and sulfapyridine, that are of great value in the treatment of various forms of meningitis.

The members of the Meningitis Division of the Bureau of Laboratories of the Department of Health of New York City have used neoprontosil and sulfanilamide for more than two years and sulfapyridine for only a few months. At this time, we can safely make some comparisons between sulfanilamide and neoprontosil. With both these chemicals, we have had very satisfactory results in treating meningitis due to the hemolytic streptococcus, the case fatality being around 20 per cent, although cases treated less than twenty-four hours are included in the series. This form of meningitis had shown a case fatality of more than 95 per cent before we began the use of these chemicals.

Pneumococcal meningitis in which the case fatality had previously been 100 per cent has been treated with less favorable results. We have had 8 recoveries in a group of 52 cases. Sulfapyridine has been used in only 7 cases with 3 recoveries. Obviously with so small a group of cases, it is not possible to draw definite conclusions in regard to the relative merits of sulfanilamide or neoprontosil and sulfapyridine in the treatment of pneumococcal meningitis. At the present time, however, we are treating all of our cases of pneumococcal meningitis with sulfapyridine.

We have also treated 20 or more cases of influenza meningitis with sulfanilamide or neoprontosil, with only 2 recoveries. We have used sulfapyridine in this form of meningitis with apparently better results—3 consecutive cases having recently recovered.

During the past two years, we have seen too few cases of meningococcal meningitis to draw any definite conclusions in regard to the relative merits of neoprontosil or sulfanilamide combined with serum or of serum alone. It is our impression, however, that these chemicals are of value in this form of meningitis and that they may be relied upon to control a septicemia without the use of serum intravenously.

It has seemed to us that neoprontosil is less toxic and quite as effective as sulfanilamide. Barlow has reported that in laboratory animals the oral lethal dose of neoprontosil is nearly seven times as great as that of sulfanilamide. We are inclined to believe that the action of neoprontosil depends on some other factor (probably the azo dye) than the sulfanilamide alone. This belief was expressed by Domagk in regard to the original prontosil, and also by Brown, Bannick, and Herrell of the Mayo Clinic in regard to neoprontosil. Moreover, neoprontosil given orally

is effective when the concentration of sulfanilamide in the blood is only 1 to 3 mg per 100 cc. This compares with a concentration of 10 mg or more per 100 cc., which most workers consider necessary when sulfanilamide is used. Moreover, neoprontosil has a wide range of elasticity in methods of administration. If patients can take and retain medication by mouth, it may be given orally in the form of tablets. This form of administration we prefer, as it is absorbed nearly as quickly as when given subcutaneously and is excreted more slowly. If oral administration is impossible, there is a 5 per cent solution which may be given intramuscularly. This solution may also be given intraspinally, diluted three or four times with sterile saline or distilled water. Sulfanilamide, on the other hand, is soluble only to the extent of about 1 per cent. This solution may be given by hypodermatoclysis, necessarily in much larger amounts, and it may also be given intraspinally. From our clinical observations, from personal reports, and particularly from the experimental work of Marshall, it appears that sulfapyridine is much more toxic than either sulfanilamide or neoprontosil.

Sulfapyridine is best given orally, but its administration is followed by vomiting in a fair percentage of patients. Although it is quite insoluble, it may be given by hypodermatoclysis in a so-called "super-saturated" solution, a liter of normal saline (0.85 per cent) being heated to boiling and a gram of the crystalline material added and stirred with a sterile glass rod. It is necessary to keep the solution well above 40 C while it is being administered. Sulfapyridine may also be given in small retention enemas.

The dose that is suggested for all these chemicals is much the same—15 grains or more every four hours in adults. In severe infections in children more than four or five years of age, the same dose may be tried. In still younger children, 10 grains every four hours may be given. When these somewhat large doses are given to young children no precaution must be spared to guard against the onset of toxic effects. Daily complete blood counts are an absolute necessity and there should be frequent determinations of the concentration in the serum, especially in administering sulfapyridine.

Since neoprontosil is apparently the least toxic of these three chemicals, we plan to continue its use in the treatment of meningitis caused by the streptococcus and the meningococcus. We shall use sulfapyridine in treating meningitis caused by the pneumococcus and the influenza bacillus until a sufficiently large number of cases has been observed, so that we can

compare the relative merits of neoprontosil and sulfapyridine in these infections. It has been our custom to use a specific serum whenever it is available, in addition to the chemical. When meningitis is secondary to a focus of infection, it is always important to eradicate the focus, if possible, by surgery.

Dr A. C. Silverman, *New York City*—The effect of sulfanilamide in scarlet fever is as yet not definitely determined. There appears to be concurrence of opinion that sulfanilamide does not affect the rash and toxemia in the way that serum does. Claims have been put forward, however, that sulfanilamide lessens the incidence of septic complications. When these claims are carefully analyzed, however, considerable doubt remains.

Probably the first report was that by Peters and Harvard in England, who treated 150 cases with sulfanilamide and used a similar number for controls, but gave serum to 56 cases of the latter. They noted that 35 per cent developed one or more complications in the sulfanilamide group as against 56 per cent in the controls. When one examines their table of complications, however, it is seen that albuminuria, rheumatism, endocarditis, and nephritis are grouped together with the more definite septic complications, when it comes to otitis media it is found that there were 11 in their treated group and 10 in the controls, hence the validity of their conclusions may well be questioned.

In our use of sulfanilamide during an outbreak of scarlet fever in 1937, we compared the effect of the drug in moderately severe cases and found 7 instances of suppurative otitis media in 19 cases which served as controls, whereas in 23 similar cases treated with sulfanilamide only 2 suppurative ear cases were noted. Wesselhoeft and Smith, in Boston, in a series of 100 cases each had 15 suppurative ear cases in the control group and only 6 in the sulfanilamide group. We agree with them that a larger series is necessary before one can eliminate the factor of chance variation that is so inherent in scarlet fever.

It appeared to us, further, that before valid conclusions could be drawn, it was necessary not only to have a large enough series, but to define criteria of the types of cases as seen on admission and as classified subsequently in the light of the course of the disease. It is also necessary to note the presence or absence of septic invasion at the time that observation begins and to separate these from the septic complications which develop later in the disease and apart from the sequelae which are not considered due

to the invasion of the streptococcus in the tissues. Needless to say, the factors of age and the season must also be taken into consideration, in addition to the length of time from the onset of illness to the beginning of clinical observation.

Applying such criteria to our 1,938 cases, there were 84 that had been admitted to the hospital within three days from the onset. Forty-three received sulfanilamide and 41 were treated without it. The ages were practically identical. The time of the year showed some variation. In the sulfanilamide group, 46 per cent were considered mild cases and in the control group 78 per cent. In the sulfanilamide group there were 22 cases that were considered moderate or severe and in the control group there were 9. Patients with septic complications numbered 20 in the sulfanilamide group and 8 in the control group.

Thus it is seen that the proportion of patients with septic complications corresponds very closely to the proportion of moderate and severe cases in the 2 groups. When attention is focussed on the suppurative ear cases it is seen that in the untreated group they number 3, or 33 per cent, among the 9 patients more than mildly ill and in the sulfanilamide group there were 4 suppurative ear cases out of 23, or 17 per cent. It could be pointed out, too, that among the suppurative ear cases in the first group there was 1 surgical mastoid but none in the sulfanilamide group, and that the suppurative ear cases were increased by only 2 after admission, although 5 catarrhal ear cases were found on admission.

Nevertheless, the small number of cases involved does not warrant definite conclusions.

Undue enthusiasm over individual cases has to be guarded against. It would be very easy, for example, to single out 2 brothers, five and seven respectively, in a family outbreak of 5 cases. Upon admission, both looked like mild cases with but slight rhinitis. Both subsequently developed suppurative otitis media, bilateral in the five-year-old, right-sided in the elder brother. Sulfanilamide was given to the younger brother and he recovered, the other, without sulfanilamide, had the only mastoidectomy in this series. Nonetheless, it is one of the most unsound tendencies in practice to draw conclusions from a single case of an inherently varying morbid process. Clinical impressions have their usefulness, and in clinical studies controls are only such in part, in view of varied and subtle individual differences which cannot be wholly equated, but conclusions can be valid only if based upon clinical experience and judgment within an acceptable statistical framework.

The ease with which sulfanilamide may be given has tended to deny serum to cases that might have benefited from its use. Physicians who tend to be wary of employing serum therapeutically often fail to be concerned over the possible taking of unwarranted risks with sulfanilamide. When one considers that in recent years about 75 per cent of our hospitalized scarlet fever cases have been mild, it seems unwarranted to employ in such cases any therapy that carries more risk relatively than the disease itself.

THE RADIO BALLYHOO

Tooth pastes and powders, cathartics, antiacids, cosmetics, and patent medicines continue to interrupt our radio musical programs and irritate us as we are listening to the latest trans-radio news. How long will the American public be so gullible, asks the *Journal of the Connecticut State Medical Society*. Just as long as there is money to be made by this kind of propaganda and the radio public will put up with the jarring jargon of these jerry-builders.

Radio advertising was given considerable prominence on the program of the conference of the Association of Food and Drug Officials of the United States recently convened at Hartford.

It was advocated that radio advertising copy be filed and subjected to the close scrutiny of food and drug officials on the same basis as newspaper and magazine advertising. Why not? The detrimental effect of radio in broadcasting misleading information is in direct violation of the

Food, Drug, and Cosmetic Act. As Dr. George R. Cogswill of Yale University said, the general impression given in radio advertising is usually erroneous and if the claims of radio advertisements were included in the written advertisements or on labels, they would be immediately considered a violation of laws.

Our neighbor, Canada, does not allow its radio audience to be duped and bored with all this ballyhoo. Are we in the United States of any less intelligence? It would be a boon to our nerves and a solace to the various parts of our anatomy to which the appeals are directed if the food and drug administrators would adopt a policy similar to that used by the Council on Pharmacy and Chemistry of the American Medical Association whereby data on food and drug products are collected and reported to the public. Surely all claims amenable to scientific tests, chemical or biological or both, should be supported by the appropriate tests.

Case Reports

ACUTE PERICARDITIS

Following a Secondary Infection of the Lymph Node of a Ghon Tubercle

BERNARD SHELIGMAN, M D, and MAX LEDERER, M D, Brooklyn, New York

(From the Medical Service and Division of Pathology, the Jewish Hospital of Brooklyn)

AN ACUTE suppurative pericarditis was found postmortem in the following case. It resulted from the perforation of a pyogenic abscess in a tracheobronchial lymph node. The bacillus tuberculosis was found in the wall of this gland, which was draining a fibrotic, pulmonary Ghon tubercle. Of particular interest, in this patient, was the clinical picture suggestive of coronary occlusion with an electrocardiogram that showed an unusually high elevation of the R-T segment in all 3 leads indicative of the superficial myocarditis accompanying the purulent pericarditis.¹

S S, a multiparous, white widow, 54 years of age, was admitted to the hospital November 26, 1936, complaining of epigastric distress of three days' duration and an attack of cyanosis, dyspnea, and clammy skin, five hours before admission.

Previous History—She had nocturia, weakness, and loss of ten pounds in the year preceding January, 1929, in which month an amputation of the cervix and perineorrhaphy were performed for a lacerated cervix and prolapse of the uterus. In May, 1929, the uterus was suspended anteriorly. Approximately two weeks after each operation, she had pain in the right lower chest, after the second, a friction rub and temperature of 102.8 F developed. She felt well until eighteen months before her last admission to the hospital. She then complained of feeling weak and tired and gradually lost twenty pounds. She was told she had a slightly elevated blood pressure. In October, 1936, the right ankle became very painful and was swollen for three days.

Present Illness—On November 19, she became weak and had a temperature of 102 F. The next two days, she tried to attend to her household duties but had to lie down frequently. Her appetite was poor. On November 23, she had pressing epigastric pain and slept poorly. The next morning she was pale, felt weak, and her skin was cold. That afternoon, she vomited once. A steady, persistent, pressing epigastric pain was present until a few hours before admission. She passed no urine the day after the onset of the pain, but the next morning the urine was scant, dark red-brown. At 5:00 P.M. on November 26, she again became pale with a cold clammy skin and her lips became blue, the epigastric pain had disappeared. Breathing increased in rate and was somewhat labored.

Physical examination revealed a woman 153 cm tall in collapse. Her temperature was 99 F and her respirations were 48 per minute. The sclerae were icteric. The veins of the neck were moderately distended. The heart was enlarged

to the left of the midclavicular line. The sounds were distant and irregular in rate and rhythm. No precordial friction rub was heard. A few crepitant rales were heard in the right axilla. The abdomen was moderately distended. A suprapubic scar was present. The liver was tender and enlarged to four fingers' breadth below the costal margin. The right great saphenous vein was thickened, firm, and tender in the leg. She had edema of the ankles.

Course—She was given circulatory stimulants and the following day her condition improved. She had a marked cough and recurrent, persistent epigastric pain which was made worse after the ingestion of small amounts of food. After an infusion of glucose, the blood pressure rose from 0 to 104/80. She had marked oliguria. During the evening and the following morning she became cold and cyanotic, the respiratory rate increased to 65 per minute and her temperature fell to 97.8 F. She suddenly became comatose and expired on November 28, at 11:00 A.M., about thirty-seven hours after her admission. Preagonal intracardiac adrenalin puncture released five cubic centimeters of a seropurulent fluid from the pericardial cavity.

Laboratory Data—(November 26, 1936) Urine—one ounce, albumin faint trace, sugar 0.2 per cent, two or three white blood cells per h.p.f., occasional hyaline and granular casts.

(November 27) Red blood cells 3,610,000, hemoglobin 70 per cent, white blood cells 19,200, polymorphonuclear leukocytes 88 per cent.

(November 27) The only electrocardiographic tracing taken showed auricular fibrillation and high elevation of the R-T segment in all leads, especially lead 2. The descending limb of the R wave was slurred in all leads (see Fig 1).

(November 28) Blood sugar 498 mg per 100 cc, urea nitrogen 71.6 mg per 100 cc, carbon dioxide 38 vol per cent, Kline test negative.

Necropsy (No 2791)—The body was well developed and weighed approximately 65 Kg. There was slight pitting edema over both lower extremities and the lumbosacral region. The right and left pleural cavities contained 700 cc. and 200 cc of thin, cloudy, straw colored fluid, respectively. There were adhesions about the right lung anteriorly. The pericardial cavity contained 250 cc of thick, yellow-green fluid, on smear, gram positive diplococci and streptococci were present and on culture there were numerous colonies of streptococcus hemolyticus.

Pericardium and Heart—The pericardial surfaces and the epicardium were covered by thick, shaggy material made up of yellow, green, and gray strands which formed a network over the whole surface and the base of the great vessels. The heart portion of pericardium, and several

FIG 1 Electrocardiogram

adjacent tracheobronchial lymph nodes weighed 500 Gm (see Fig 2). The valve leaflets were slightly thickened. The coronary ostia and vessels were normal and patent. On gross appearance the cut surface of the myocardium was normal.

Lungs—Near the apex of the upper lobe of the right lung, there was a circumscribed firm gray nodule, 1.3 by 0.8 cm (Ghon tubercle). The mucosal lining of the trachea was dark red and granular.

Tracheobronchial Lymph Nodes—The tracheobronchial lymph nodes were soft, gray-black, and measured up to 4 by 2 by 1.3 cm. The largest one was hard and situated in the angle between the trachea and right bronchus. It consisted of a partly calcified shell up to 0.4 cm in thickness surrounding a cavity containing creamy yellow-green material. Between the left side of the node and the ascending aorta there was a cavity 2 by 1 cm, filled with yellow-green purulent material, the lining was rough. It joined the cavity of the calcified node by a narrow tract. Through a small opening on its ventral aspect it communicated with the pericardial sac.

Spleen—The spleen weighed 260 Gm and was firm.

Microscopic Notes

Pericardium and Heart—The connective tissue of the parietal pericardium was loose and infiltrated with numerous polymorphonuclear leukocytes, small round cells, and large mononuclear cells. The inner surface was covered with a thick layer of pink staining strands enclosing polymorphonuclear leukocytes and some extravasated blood. Occasional clumps of bacteria were noted among the polymorphonuclear leukocytes. The epicardial surface was covered by a fibro-purulent exudate. Except where the epicardial fat was thick, the fibrino-purulent exudate extended into the surface of the myocardium of all the chambers of the heart. At numerous points, capillaries and strands of fibroblasts extended into the epicardium from the overlying layer of fibrin. The deeper layers of myocardial fibers

were of good size. The intermuscular connective tissue was slightly increased. In scattered areas, isolated myocardial fibers lay embedded in broad strands of connective tissue.

Lungs—The interalveolar septa were broad and wavy, the capillaries were distended with blood. In some areas the septa were close together. The epithelium of the bronchioles was desquamated and the walls in places were infiltrated with polymorphonuclear leukocytes and small round cells. There were deposits of coarse black particles about the larger blood vessels.

Tracheobronchial Lymph Nodes—In a preparation from the upper portion of the node situated in the angle between the right bronchus and trachea there was no remnant of lymphatic structure. The cavity contained amorphous pink staining material, polymorphonuclear leukocytes and cellular debris. The inner portion of the wall was broad and consisted of loose and more dense hyalinizing fibrous connective tissue with small round cells, large mononuclear cells, areas of calcification, and spicules of bone. Beyond this layer there was a zone of loose fibrous connective and adipose tissue also containing accumulations of small round cells and large mononuclear cells. Staining by the Ziehl-Neelsen method revealed several acid-fast bacilli.

Spleen—The spleen showed evidence of passive congestion.

Incidental findings were melanosis of the esophagus and lipomata of the sigmoid colon.

Anatomical Diagnosis—Primary tuberculous nodule in lung (right) (Ghon), tuberculous lymphonodulitis,* mediastinal with suppuration, abscess formation and perforation into the pericardial sac, pericarditis, acute fibrino-purulent**, tracheobronchitis, acute, passive congestion of viscera, acute, bilateral pleural effusion, edema of lower extremities, splenomegaly.

Secondary scar of uterine suspension and cervical amputation, fibrinous pleural adhesions (bilateral), latent phlebitis right saphenous vein.

Comment

In this woman of 54, a state of lowered resistance was followed by the occurrence of a nine-day hemolytic streptococcus infection which was superimposed upon tuberculosis of a tracheobronchial lymph node draining a Ghon tubercle of the lung. An abscess of this hilar gland perforated into the pericardial sac. A slight rise in temperature was present at the onset. Epigastric pain, vomiting, dyspnea, tachypnea, pallor, weakness, cyanosis, clammy skin, and zero blood pressure were the outstanding symptoms. The pain disappeared after the perforation only to recur with the appearance of a suppurative pericarditis. Marked congestive failure also occurred.

The clinical picture was that of coronary occlusion or of a visceral perforation. However, the electrocardiogram showed markedly positive deflections of the R-T segment in all three leads especially prominent in lead 2. The descending

* Bacillus tuberculosis on smear

** Streptococcus hemolyticus on culture

SUPPURATIVE MEDIASTINAL
LYMPHODULITIS AND PERICARDITIS

FIG 2 Needle has been passed through gland abscess into the pericardial cavity through the perforation

limb of the R wave was slurred. No Q wave was seen. Auricular fibrillation was present. A purulent pericarditis amounting to 250 cc and subepicardial myocarditis were found post-mortem. The coronary vessels were normal.

In coronary occlusion the distinguishing features of the electrocardiogram are the elevations of the R-T segments in two leads only. A reciprocal depression of the R-T sector occurs in lead 1 as compared to lead 3 or vice versa. A Q wave may be present.³ A similar electrocardiographic pattern to the one observed in this case might be found if both coronary arteries were involved,³ with diffuse myocardial damage in infectious disease, and following the use of drugs which affect the entire coronary circulation.⁴

Summary

A woman of 54 died as the result of a purulent pericarditis with superficial myocarditis and symptoms suggesting coronary thrombosis. The pericarditis was subsequent to the perforation of a secondary abscess in a tuberculous mediastinal lymph node. The electrocardiogram showed a positive deflection of the R-T segment in the three limb leads and slurring of the descending portion of the R waves.

GAUCHER'S DISEASE

Associated with Multiple Telangiectases in an Elderly Woman

H F WECHSLER, M D, and E GUSTAFSON, M D, New York City

(Adjunct Physician and House Physician, respectively Lenox Hill Hospital)

ALTHOUGH Gaucher's disease is not rare, the number of cases actually reported in the literature is not great. Hoffman and Maller¹ were able to collect but 89 cases up to 1929. The following case merits publication not only for this reason but because of several unique features.

Case Report

S C, Jewess, 68 years of age, was admitted to the Lenox Hill Hospital April 4, 1936, complaining of painful black and blue spots on both legs. Her present illness dated back to eight years ago, at which time, following injury to one of her lower extremities, she developed ecchymotic spots which finally disappeared after prolonged bed rest. She was told at that time that she had a large spleen but states that she had been aware of a large mass in her abdomen for twelve years previously. The ecchymotic spots have returned intermittently ever since. The last attack occurred six months ago and has persisted in spite of bed rest and medication. The areas have increased in size and painfulness. Her appetite during her present illness has been very poor and her diet has consisted almost entirely of milk and crackers. Her bowel movements have been infrequent and small in amount.

The patient had always been in good health except for the purpuric manifestations noted above and a severe attack of bronchitis ten years ago. She had had occasional epistaxes which she attributed to picking her nose. Her skin has always been a deep brownish hue. Her menstrual history was normal. The menopause occurred at forty-eight years of age.

There was no history of familial diseases. Her mother died at ninety-five and her father at 108. Two brothers are alive and well. One brother died of typhoid, one of tuberculosis, and a third of a stroke. One sister died of "hip disease."

Physical examination revealed a short, poorly developed and nourished, elderly, white female, appearing chronically ill. The skin showed a diffuse brownish pigmentation, which was marked even in unexposed areas. There were numerous dark brown freckles, especially over the face and arms. Many small telangiectases were present especially on her upper extremities and abdomen. There was a rather marked loss of subcutaneous tissue.

The pupils were equal, regular, and reacted to light and accommodation. There was no exophthalmos, lagophthalmos, nystagmus, or weakness of the extrinsic muscles. Pingueculae were present in both sclerae. The conjunctivae were clear but somewhat pale. No telangiectases or cause for epistaxis were seen in the nose. On the buccal mucous membrane and lower lip were a few small areas of brownish pigmentation.

The tongue was rather smooth with slight atrophy of the papillae. Numerous telangiectases were present on the dorsal and inferior surfaces of the tongue (Fig 1), none of which were larger than 3 mm in diameter. They were more marked on the left half of the tongue. One was also present on the left buccal mucosa. The gums were atrophied. The pharynx was negative.

The thyroid was not palpable. There was no glandular enlargement. The veins were distended but did not fill from below.

The chest was of normal configuration. The breasts were atrophic and tender but no masses were felt. The lungs were hyperresonant throughout. Breath sounds were vesicular in character with a prolonged expiratory murmur. No adventitious sounds were heard. The apex beat of the heart was visible in the fifth intercostal space, 7½ cm from the midsternal line. The heart sounds were of good quality and regular. A soft systolic murmur was audible at the apex. The radial arteries were not thickened. The pulse rate was 82. The blood pressures were 120 systolic over 70 diastolic.

The abdomen was somewhat distended. The liver was barely palpable and not tender. The spleen was greatly enlarged and extended down to the left iliac crest and almost to the midline.

Both legs showed extensive ecchymoses over the anterior surfaces, most marked in their proximal halves. A few smaller ones were visible on the anterior aspect of the left thigh. These areas were extremely tender.

The reflexes were physiologic.

The anus showed a deep brown pigmentation. There were no telangiectases visible in either anus or rectum.

Laboratory Data—Blood count: Hb (Sahli)—70 per cent, rbc, 3,300,000, wbc, 1,400, polymorphonuclears, 81 per cent, lymphocytes, 14 per cent, monocytes, 3 per cent, basophiles, 2 per cent, color index, 1.06, platelets, 100,000.

The bleeding time was 7 minutes, the clotting time was 5 minutes, and the prothrombin time was normal. The tourniquet test (Rumpel-Leede) was positive. The plasma fibrin was 385 mg per cent.

A fragility test of the red blood cells showed slightly increased resistance to hemolysis.

Blood chemistry: urea nitrogen, 8.6 mg per cent, creatinine, 0.05 mg per cent, uric acid, 1.6 mg per cent, sugar, 85 mg per cent, serum calcium, 8.6 mg per cent, serum phosphorus, 2.8 mg per cent, cholesterol, 139 mg per cent, plasma sodium, 270 mg per cent (117 me.) and 320 mg per cent (131 me.), CO₂, 40.4 vol per cent.

The blood Wassermann was negative.

The icteric index of the serum was 10.

Urinalyses revealed specific gravities ranging from 1.009 to 1.025, 1 to 2 plus albumin, a moderate number of scattered and clumped pus cells.

From the Medical Service of Dr Otto M. Schwerdtfeger, Lenox Hill Hospital.

FIG 1 Drawing showing telangiectases of the tongue and buccal mucous membrane.

A gastric analysis showed a free acid of 61 equivalents and a total acid of 76 equivalents.

Examination of the stool was negative for blood on several occasions.

A galactose tolerance test for liver function was normal, 0.04 Gm being excreted in five hours.

Roentgenograms of the lower extremities showed a rather marked degree of cortical atrophy of both tibiae, particularly in the upper and lower fourths. The lower femora showed similar changes. The walls of the blood vessels were heavily calcified. A roentgenogram of the chest revealed the cardiac and aortic shadows to be slightly widened in all diameters and calcific deposits in the mediastinal nodes of the left hilum. A flat plate of the abdomen was negative except for extensive, mottled, calcific deposits on the left side just above the crest of the ilium.

A biopsy of the skin of the forearm was reported as follows: "In the basal layer of the surface epithelium, the cells contain a brownish granular material. The pigment is within the cells and none is present in the surrounding tissue. The pigment has the following negative characteristics: it does not give the Prussian blue reaction, it is not a lipid (hemofuscin), it does not give the reaction for oxidizing granules (dopa reaction). It is blackened by silver nitrate (melanin and its derivatives)."

A splenic biopsy was performed with the Hoffman punch. The pathologist's report follows: "Microscopic examination (Fig 2) shows splenic tissue, including capsule, which is much thickened by fibrosis. The splenic pulp is reduced in amount and scattered through it are numerous small and larger masses of large, round, or polyhedral cells with small centrally placed nuclei and abundant acidophilic cytoplasm which is either coarsely granulated or vacuolated. These cells correspond to the characteristic cell of Gaucher's disease."

Blood counts taken before and after the subcutaneous injection of 5 minims of adrenalin showed the following:

	W B C	P	L	M	E	B
Before Injection	4,200	80	16	4	0	0
15 min after	12,050	60	36	4	0	0
30 min after	9,800	68	28	4	1	1
45 min after	7,000	78	18	3	1	0

Course—Because of her markedly restricted diet, there arose the possibility that the hemorrhagic diathesis was related to deficiency of vitamin C. She was placed on a high vitamin C diet and a course of cevitamic acid intravenously was instituted, with, however, no effect on the tourniquet test or the ecchymoses.

The first determination of the blood sodium was low and the report on the skin biopsy showed the pigment to be a melanin or a melanin derivative. Although Addison's disease could not adequately explain the clinical picture, it was decided to test this possibility by placing her on a low sodium diet. No effects were noted.

The remaining therapy consisted of a high vitamin diet, liver, and iron. The ecchymoses were gradually absorbed but some stiffness of the left knee resulted, requiring orthopedic care.

Comment—As autopsies on the newborn have demonstrated, Gaucher's disease is characterized from the very onset by a diffuse involvement of the reticulo-endothelial system. According to Pick,² there are but two factors that alter the clinical picture of the disease: the participating curve of the organs, which determines the clinical type, and the rate of growth of the disease. How exquisitely chronic the rate of growth can be is exemplified by our patient who was 68 years of age at the time the disease was discovered. That such chronicity is not unique is shown by the case recently reported by Bessie,³ who was

62 years of age at the time of observation. Horsley, *et al.*,⁴ have tabulated in 71 cases the ages at which the disease was first noticed and they list 9 cases, including their own, who were 30 years of age or over. The eldest was 56. Gaucher's disease must, therefore, be considered in the differential diagnosis of splenomegaly regardless of the patient's age.

Another interesting feature of our case was the multiple telangiectases exhibited by the patient. A diagnosis of Rendu-Osler-Weber's disease⁵ complicating the Gaucher's disease was entertained at first. The absence of a hereditary familial history and the lack of relationship between the purpura and the telangiectases, however, made this assumption untenable. Although she suffered from epistaxes, no telangiectases were found in the nose and the patient herself attributed them to trauma. Fitz-Hugh⁶ has described 4 cases of hereditary hemorrhagic telangiectasia associated with enlargement of the liver and spleen and has collected several others from the literature. They bear no resemblance to our case except for the similarity in blood group (O). In his only autopsied case, the spleen showed a chronic hyperplasia with fibrosis and numerous areas of hemorrhage. The telangiectases shown by our patient are best considered as a senile manifestation. That we were unable to find any mention of them in the literature on Gaucher's disease would then be explicable, as the reported cases comprise on the whole a much younger age group. Her hemorrhagic diathesis is adequately explained by the thrombocytopenia.

There is little reference in the literature to the nature of the skin pigment in Gaucher's disease. It is generally held that the pigmentation of the internal organs is derived from the increased blood destruction constantly present in the disease. In the hematopoietic and lymphatic systems, it consists predominantly of hemosiderin, although iron-free pigment is also occasionally found outside of these structures. With regard to the pigmentation of the skin, Pick² merely states that it is an autogenous pigment and is an expression of the hemachromatosis. The chemical tests performed on the patient's skin removed by biopsy indicated that it was melanin or a melanin derivative.

Because of her age, Gaucher's disease was not seriously considered at first in the differential diagnosis. It was soon realized, however, that the galaxy of signs exhibited by the patient, such as pigmentation, pinguiculae, hypochromemia, leukopenia, thrombocytopenia, purpura, enlarged spleen, and changes in the long bones could fit into no other clinical syndrome. We

FIG 2 Photomicrograph ($\times 300$) of tissue obtained by splenic puncture showing Gaucher's cells

decided, therefore, to clinch the diagnosis by means of a splenic puncture. Although not entirely devoid of danger, at least 6 cases have been successfully diagnosed by this procedure.⁷ Following the puncture, alarming symptoms of collapse appeared from which, however, she quickly rallied.

Summary

1 A case of Gaucher's disease in a Jewish female, aged 68, is reported as the eldest thus far recorded in the literature.

2 The unique association of the disease with multiple telangiectases and their probable senile origin is discussed.

3 The skin pigment was shown to be melanin or a melanin derivative.

4 The diagnosis of Gaucher's disease was confirmed by a splenic puncture.

. . .

The patient was again admitted to Lenox Hill Hospital in the spring of 1939 with a recurrence of purpuric manifestations. The laboratory workup was essentially the same. A moderate anemia was present and the patient was treated supportively with high vitamin diet, cevitic acid, and liver extract intramuscularly. She was discharged much improved after a short stay in the hospital. Her present age is 71 years.

CHRONIC GASTRITIS CAUSED BY GASTRIC BEZOAR

MAX WEITZEN, M D, New York City

THE object of this report is chiefly a brief discussion of an unusual and unique case which was characterized, especially, by a peculiar set of symptoms pointing toward more than one disease manifestation. The predominating high lights for critical consideration were those of active duodenal ulcer, advanced thyrotoxicosis, and hypoglycemic reaction suggesting pancreatic hyperfunction. The true state of affairs, however, revealed itself inconspicuously and when least expected. The case proved to be one of the so called rare instances of gastric bezoars.

Bezoar is the term applied to the masses found in the stomachs and intestines of animals and men. The ancient Arabians called it *badzehr*, denoting antidote. It was highly valued by virtue of their belief in its power to counteract poison. Bezoars of the human beings are classified into three varieties¹ trichobezoars, composed of hair balls only, trichophytobezoars, composed of hair balls and vegetable fibers, and phytobezoars, composed of vegetable fibers and concretions. The cause of bezoars may also be traced to the swallowing of skins, seeds, fatty acid crystals, shellac, bismuth, and other mineral salts. The muscular contraction of the stomach kneads and molds the swallowed plastic material into casts or balls. It may occur in persons with mental aberration as well as in those of perfectly sound mind.

Symptoms denoting the presence of these foreign bodies bear no characteristic pattern. They depend, essentially, upon the size of the mass, irritability of the gastric mucosa, secondary ulcer formation, or development of chronic gastritis. Epigastric pain relieved by food or alkalies, however, is a fairly constant symptom. This may be associated with flatulence, nausea, vomiting, and irregular bowel action. Gastric analysis has no clinical value in this condition, achlorhydria may alternate with hyperacidity at different times. In the large-sized bezoars, a palpable upper abdominal tumor is readily disclosed, thus greatly adding to the confusion with regard to differential diagnosis.

Roentgen examination, likewise, offers no conclusive diagnosis. At best, this may reveal the presence of a foreign body when of considerable size. When secondary ulcer or extensive gastritis dominates the picture, small bezoars may never be suspected as the causative agents

of the existing disorder. Surgical exploration or spontaneous evacuation is usually the more common mode of obtaining a definite diagnosis.

Case Report

P. A., aged twenty-two, married, had had no pregnancies and had never complained of any digestive disturbance prior to the onset of the present illness. One year ago she was suddenly seized with severe epigastric pain after eating a dish of shrimps and was relieved by treatment a few hours later. During the year she had several similar episodes, after eating other kinds of food, but she was completely relieved within a short time. She enjoyed total freedom from any gastric symptoms during the intervals. About one month ago her symptoms assumed a changed aspect. Severe localized epigastric pain appeared day after day, two or three hours after each meal. This was associated with nausea and occasional vomiting, continued belching of gas, and unbearable flatulence. She also complained of heat sensation and increased perspiration, weakness, air hunger, fatigue, and annoying frequency of micturition.

Most bizarre of all her symptoms was a constant craving for any and all kinds of food. General comfort and satisfaction was obtained by nothing but continued eating and drinking. However, she had failed to maintain her former weight. She had lost ten pounds within that month. Her nights were undisturbed by any discomfort whatsoever.

Physical examination revealed nothing tangible upon which to base any tentative diagnosis. Offhand, one was justified in suggesting the existence of an active duodenal ulcer. On further reflection, however, this was offset by the absence of characteristic periodicity and seasonal recurrence, response to neutralization by alkalies, nocturnal discomfort, and other specific features commonly associated with peptic ulcer.

Evidence of increased oxidation, as indicated by her loss of weight despite increased consumption of food and increased production of heat and excessive perspiration, was indeed highly suggestive of thyrotoxicosis, hyperinsulinism associated with pancreatic disease, or the syndrome of hypoglycemia with an abnormal response to sugar tolerance test in the presence of ulcer symptoms.² This, again, failed to materialize. She had no thyroid enlargement, no exophthalmos or lid-lag, no tachycardia or characteristic blood pressure, no marked nervous irritability or fine tremor of hands, and no abnormal blood sugar curve.

Roentgen examination occasioned further confusion of the issue at hand. No evidence of ulcer was discernible in any position. The stomach and duodenum appeared normal in size, shape, and activity. The mottled circular form of the fundus attracted but little attention at first (Fig. 1). After partial evacuation, however, films taken in the right oblique position

FIG 1 Normal stomach and bulb Slightly mottled circular cardia.

revealed a more generalized mottling throughout the entire proximal half of the stomach, not unlike a generalized polyposis or pseudopolyposis of chronic gastritis (Figs 2 and 3). This deduction obtained corroborative evidence by the two-hour film. The swollen longitudinal folds of mucous membrane, significant of extensive gastritis, abruptly terminated at the margin of the mottled circular cardia. Finally, the well-filled duodenal bulb revealed a small fleck on the lesser curvature, apparently a shallow secondary ulcer crater.

The true significance of this swarming train of symptoms however was disclosed during the performance of a gastric analysis. A number of small black bodies enmeshed within thick mucus, were found in the fasting stomach contents. The consistency of these bodies was that of fragments of old clotted blood, apparently retained between the thickened folds of mucous membrane. Eighty cc. of this material were obtained at that sitting. It consisted, for the most part, of heavy tenacious mucus and a small amount of fluid gastric juice. This had a free acidity of twelve and a total acidity of twenty-eight. A benzidine test, however, was entirely negative.

One of these black bodies was soon examined microscopically. Instead of blood elements they proved to be composed of a mixture of fibers of unequal thickness and reflecting blue pink, and brown colors. The very thin fibers were identified as those of human hair, while those of heavier caliber had no distinctive pattern (Fig 4). They were analogous to the remains of a disintegrated piece of cloth, originally composed of a diversity of colored threads. The presence of a swallowed foreign body and its retention in the stomach formed an indisputable fact. Owing to the rarity of the condition, however, Dr Alfred Plaut, pathologist to Beth Israel Hospital was kindly requested to examine the same slide. His report was nothing but confirmative, specifying additionally that the heavier fibers consisted of a mixture of variously colored cotton and wool threads.

FIG 2 Rapidly emptying stomach. Note the appearance of gastritis verrucosa or pseudopolyposis.

FIG 3 Two-hour film. Note enlarged circular cardia and irregular swollen rugae.

The final diagnosis was no further mystery. Obviously, all her symptoms could readily be ascribed to the constant irritation induced by the presence of a gastric trichophytobezoar. Progressive development of chronic gastritis was the primary pathologic factor. The hypochlorhydria, secondary anemia, and the increased bowel action were inevitable sequelae responsible for her deficient digestion and utilization of the

FIG 4 First portion of bezoar obtained through the stomach tube Highly enlarged

FIG 5 Second and larger portion of bezoar Dislodged by stomach tube and appeared by vomiting Slimy mucus surrounding the strands.

excess food by the overburdened and irritable stomach. The secondary duodenal ulcer apparently played a minor role in the production of this complex symptomatology.

The patient's ready cooperation was a direct aid to the final solution of the problem. She had acquired the habit, unconsciously, of biting and swallowing the ends of the different threads during her work of sewing on hundreds of labels on finished white-goods garments. This was continued every day for several years. She modestly conceded, however, that she also enjoyed biting and chewing "other things."

She made a complete recovery and gained strength and weight on a comparatively mild medical regimen and continued gastric lavage.* A much larger portion of that extraneous material was brought to light for our mutual benefit (Fig 5).

Comment

Cases presenting atypical symptoms and signs of digestive disturbance are not of uncommon occurrence.

* To date, January, 1940 the patient has had no repetition of any symptoms of digestive disturbance. This proves conclusively that her prior symptoms were caused by nothing but the presence of the bezoar.

These, for lack of concrete evidence, are usually designated as nervous indigestion or other applied terms, especially so in the younger adults of modern times. This case, therefore, may rightfully serve as a stimulus to bear in mind the prevalence of like habits with innumerable other workers in the needle trades. The problem of the etiologic factor responsible for certain obscure cases of indigestion may occasionally be solved with more ease.

EXTREME FATIGUE OR EXHAUSTION AS A SOLE SYMPTOM OF HEART FAILURE

JULIUS A OSHLAG, M D, New York City

(From *Riker's Island Hospital, Department of Correction, New York City*)

IT HAS been denied that left ventricular failure may first be manifested by fatigue or a sense of exhaustion. MacKenzie¹ states that exhaustion due to an ineffective heart beat rarely occurs and then only in extreme cases of heart failure and advises that if the limiting sensation be exhaustion a careful scrutiny be made for causes other than the heart. Other authors^{2,3,4} describing the early symptoms of cardiac insufficiency fail to mention this symptom, stressing instead, the more commonly observed symptoms of failure behind the affected ventricle.

On the other hand, Harlow Brooks⁵ states "One of the less frequently recognized symp-

toms, especially by the patient himself, is exhaustion and loss of strength. This state may exist often for a very long time without the appearance of other signs or symptoms likely to arouse the apprehension of the patient." There are other descriptions of the appearance of this symptom^{7,8,11} and of its physiologic basis.⁹

It was felt that the unusually long period of time during which fatigue and exhaustion dominated the clinical picture justifies the report of the following case.

A D, an unmarried white female housekeeper, aged 46, was first seen on June 2, 1936. She complained of a feeling of exhaustion and of hav-

ing been extremely tired and sleepy for the past four or five months. After sleeping soundly for eight to ten hours she would arise to find it too great an effort to dress completely. Ten minutes of housework necessitated a rest of at least twenty minutes. She took long naps during the morning and afternoon, and indeed found it difficult to resist sleeping at almost any opportunity. On two occasions she had fallen asleep in the subway and had been carried past her destination. Walking a flight of stairs made her breathe hard but the actual limiting symptom was fatigue and not dyspnea. There were no palpitations, precordial pain, orthopnea, or other symptoms relative to the cardiovascular system. Her habits were good and her past history was negative except for measles in childhood and neuritis at age 31. She had one brother who died at the age of 37 of pneumonia and one sister who died at the age of 35 of childbirth. Both of these were said to have had heart disease, but the type was not known.

At a much later date the patient admitted that some eight months prior to the date on which she was first seen, after experiencing the same symptoms for approximately two months, she had visited a physician in a distant city who had studied her extensively and finally given her digitalis apparently as a diagnostic test. She improved remarkably with this and felt quite well until a short time after she had finished the medicine. Unfortunately she did not recall the name of the physician nor, until reminded, the name of the drug, and thus no data was available from this source.

General physical examination on the day of her first visit was essentially negative except for slight obesity and changes suggestive of very early sclerosis observed in the fundus of the eye. Blood pressure was 162/98. Pulse rate and ventricular rate, 84. Heart sounds were of good quality, $A_2 > P_2$. There was a soft low-pitched systolic murmur at the apex, not transmitted and present in both the erect and supine positions. The apex was in the fifth intercostal space, 10.4 cm. to the left of the midsternal line and outside the midclavicular line. There was regular sinus rhythm. Fluoroscopy revealed an enlarged left ventricle.

During the next month the symptoms and findings noted above did not change and the following laboratory data was obtained: urine negative, Wassermann negative, blood count showed a very mild secondary anemia, electrocardiograph including lead IV negative, cardiac mensuration TTW 25.1, ML 10.1, MR 4.4 LDH 13.6, basal metabolic rate plus 9, blood urea, NPN, creatinine, and sugar were within normal limits.

On nonspecific treatment including mainly weight reduction and an iron tonic there was some very slight improvement though the fatigue remained a definitely limiting symptom.

On February 16, 1937, after an absence of about five months she returned presenting practically the same symptoms as she had on her first visit. On this date digitalis was commenced and the name of the drug reminded her that she had taken it before. When she returned a week later all of her symptoms had disappeared. This was the first time she had been able to get about her daily routine without the sense of fatigue since she had run out of the digitalis tablets pre-

scribed by the physician who had seen her in the distant city. On February 23, 1937, she was advised to take a grain and a half tablet daily and to return regularly until such time as a maintenance dose might be established.

Despite this instruction she did not again return until July 8, 1937. She stated that she had taken the digitalis regularly up to the first week in April when she ran out of tablets. From that time on the symptoms gradually returned until at the time of this visit she was so weak and tired that she had not the strength to brush her teeth completely without resting at least once during the process. She was again digitalized and within a week was quite well.

On July 27, 1937, she stated that she had been faithfully taking the digitalis but that several days before this date she had given her house an entire cleaning, moved furniture and run up and down stairs frequently, following which she had had an attack of shortness of breath and had coughed. She had no return of the sense of fatigue but the shortness of breath on walking up half a flight of stairs had continued. In addition there was some vertigo on stooping.

Examination on this date revealed in addition to findings noted above a few moist rales at the bases of the lungs and a very mild pretibial edema. The level of digitalis was raised and the maintenance dose slightly increased. When last seen on September 16, 1937, she was still without symptoms.

Comment

There can be little doubt that the symptoms presented were a result of failure of the heart for they were thrice relieved by digitalis and reappeared when the drug was stopped, whereas other medication had little or no effect. Had the symptoms not been cardiac in origin, digitalis would have had no effect and indeed, with the diminution of output* distressing symptoms might have been added. Additional evidence that the fatigue was a result of cardiac insufficiency is found in the frank backward failure presented after the third digitalization and relieved by raising the digitalis level.

The sensations of fatigue and exhaustion indicate the presence of oxygen debt and of accumulation of the byproducts of muscle activity.^{2,10} In the normal individual an augmentation in minute output compensates for the production of fatigue bodies up to a certain point and there is no sensation of fatigue. Absence or notable diminution of this reserve power must be considered as a failure of the left ventricle and in the case of fatigue as a "forward failure."

It is difficult to understand in the above case why there should be such marked forward failure without the commonly found respiratory symptoms of failure behind the left ventricle. One may fall back upon the explanation of individual variations in sensitivity to various impulses and postulate an undue central nervous system sensi-

tivity to fatigue bodies That this is not wholly adequate may be noted in the case reported above by the final appearance of full blossomed left ventricular failure, the symptoms of which were recognized and reported by the patient

Summary

A case is presented in which excessive fatigue or exhaustion appears as the only symptom of cardiac insufficiency for a matter of approximately 23 1/2 months

DR LONG TO ADDRESS THE GREATER NEW YORK DIETETIC ASSOCIATION

The annual meeting of the Greater New York Dietetic Association will be held in Hosac Hall, the Academy of Medicine, 2 East 103rd Street, New York City, on February 7 at 8 30 P M

Dr Cyril N H Long, Sterling Professor of Physiological Chemistry at Yale University, has

received special recognition for his literature and lectures on the influence of the endocrine glands on metabolism His subject for the evening will be "Recent Research on the Control of Metabolism by the Endocrine Glands"

Professional friends interested in dietetics are cordially invited to attend the meeting

Special Article

TWO UNPUBLISHED LETTERS OF DR. FELIX PASCALIS

HOWARD R. MARRARO, Ph D, Columbia University, New York City

THE New York Historical Society has two unpublished letters by Dr Felix Pascalis on two interesting medical and public health subjects. The first letter dated New York, April 7, 1823, addressed to the Honorable G C Verplanck,¹ deals with the appointment of a resident physician in New York City—a position for which he was applying. The second letter dated New York, March 22, 1825, addressed to the Honorable Clarkson Crolius,² deals with the education of apothecaries and the manufacture and sale of drugs.

Felix Pascalis-Ouvrière, the author of these letters, was born about 1750 in France. After receiving his medical degree from the University of Montpellier, he practiced medicine among the French colonists in Santo Domingo. In 1793, when the slave insurrection broke out, he was forced to escape. Together with other refugees, he settled in Philadelphia, where he practiced medicine during the next seventeen years. He was a prolific writer on medical subjects. Until 1801 he signed his name as Pascalis Ouvrière, but in that year he began to call himself Felix Pascalis. His wide experience with yellow fever during his residence in the West Indies qualified him to write with authority on that disease, of which there were several severe outbreaks in Philadelphia during that period. In 1796 he published *Medico-Chymical Dissertations on the Causes of the Epidemic Called Yellow Fever* and on other medical subjects.

A follower of Benjamin Rush, Dr Pascalis at first believed in the domestic origin of the disease, but later, in 1805, after a trip to Cadiz and Gibraltar to study the diseases of warm climates, he changed his views and believed that yellow fever was imported by fomites carried in ships.

About 1810 he left Philadelphia and moved to New York, where he lived until his death in 1833. He was closely associated with Dr Samuel L. Mitchell, becoming one of his co-editors on the staff of the *Medical Repository* from 1813 to 1820. He was greatly interested in botany and was one of the founders and at one time president of the New York branch of the Linnaean Society of Paris. His interest on the subject of the danger of urban burials led him to

publish, in 1823, a book in which he advocated the construction at a distance from every large city of a "Polyandrium" or general cemetery, where all the dead of the city should be interred in hermetically sealed vaults. Since the "Polyandrium" was to be located at a distance from the city, a series of stations, which Pascalis called "luctuaries" were to be built at suitable intervals to afford opportunities for the cortège to rest. In his book he stated that a company was being organized to carry his ideas into effect.

In the following letters the spelling, punctuation, and syntax occurring in the originals have been retained.

Felix Pascalis to G C Verplanck

New York, April the 7th 1823

Sir

I take the liberty of addressing you to solicit the good effects of your kindness and of your official influence in a circumstance particularly interesting to this City, I mean the appointment of the *Resident Physician*.

I transmitted sometime ago my humble petition to His Excellency for the honor of his nomination to that Office. I also availed myself of the politeness of the Hon^{ble} Walter Bowne³ to put in his hands several papers and documents relative to myself. But from another quarter I have been informed that in the selection of a proper person, the Governor⁴ would not fail consulting the Gentlemen of the New York delegation. I therefore call on you, Respected Sir, requesting your interest in the occasion, as far as it may not be otherwise engaged.

However Honourable a public professional trust may be, I confess that the duties of this are peculiarly so responsible, while it exposes at all times the incumbent to the conflict of various opinions, that I never felt much encouraged to place myself on the line of Candidates in the health department. Nor would I do it at present but for the following reason and motive.

By the inclosed paper, you will understand that I have advanced certain novel views and principles in explanation of the causes and operation or diagnosis of the yellow fever on the human system.⁵ It was late in the season of the elapsed year, when I was struck by the analogy between the symptoms of that disease and those which must take place when the laws of respiration can no longer afford animal heat, nor sufficiently decarbonize the venous blood. I had therefore no opportunity to add to my theory, the *experimentum crucis*, that is, the cure of this pestilential fever by obvious means that might restore animal heat and continue the decarbonizing proc-

ess of the lungs, and for procuring such facts, the official situation of a resident physician, would be the only favourable, there always being sporadic cases of yellow fever in the City and others in the Lazaretto, under his observation ⁶

If these results can ever be obtained all mysteries and problems in the generation of this disease are unravelled and resolved. A great step is made towards the preservation of mankind, against one of the worst pestilences. As yet, Sir, I could not discover any objection against my hypothesis and I further have obtained important medical authorities for its illustration.

I beg you to accept my best wishes for the preservation of your health and labours, with the assurance of the most respectful sentiments,

Sir,

Of Your H^{ble} & Obed^t Serv^t
(Signed) Felix Pascalis, M D

in Assembly
Albany

Felix Pascalis to Clarkson Crolius

New York March the 22d 1826

Honoured Sir

You will perceive by the inclosed petition or memorial of the incorporated Medical Society⁷ that it has long been our wish and determination to correct the evils complained of in the preparation and Sale of medicines. By this time we might have been successful in our design, had not many individuals set forth their own views for establishing another monopoly in a professional branch, instead of a plan for procuring instruction and competency to those who are to exercise it. Better to cover their object of a speculating enterprize, they have produced a *Report and a Petition* exhibiting nothing but the evils as aforesaid and the necessity of a remedy and thereby have obtained the Concurrence of many respectable individuals. But the bill before the Hon^{ble} the Assembly bespeaks loudly that nothing else could be obtained by it but a privileged stock for the sale of medicine without regulating the instruction and the license of those who are to prepare and sell medicines ⁸

The task of inspection attributed by the Bill to the Presidents of our medical institutions would be of no avail for meliorating the present condition of our Apothecary Shops, because we are not judges of drugs imported and stored up. The wholesale dealers are the most competent judges of such articles and it is not from them that the abuses of pharmacy have proceeded, but it is from the retailers who are either not rich enough to procure the best drugs and chemicals, or are not sufficiently qualified to prepare medicines

The want of a well informed and Professional Apothecaries in the City obliges the Gentlemen of the Faculty to provide in their respective offices a small Pharmacy on the nature of which and practical use they have been instructed. But this task is interfering very much with their medical and surgical avocations, and they would be glad to abandon it to regular Apothecaries and thereby to increase their business, if they were equally qualified and instructed as they are themselves. The respective Professions will then be placed on the footing they ought to obtain and which they have already in Philadelphia and among the most civilized nations.

I can assure you, Dear Sir, that the medical County Society will not abandon their views and intention on this important subject. We hope that another year, with the concurrence of the State Medical Society, with that of many respectable Druggists who have a correct understanding of the matter, and with the parental wisdom and authority of the Legislature, a wholesome system and preservative regulations will be obtained for the preparation and Sale of medicines and for the improvement of a Professional branch of the healing art.

Permit me to subjoin and express my sincere wishes for your health and prosperity and of the affectionate and respectful sentiments of your Neighbour and Humble Serv^t

(Signed) Felix Pascalis, M D

Corresp^t Secret^t
of the Med Soc^y

In rear

Clarkson Crolius Esq^r

The Hon^{ble} Speaker of the House of Assembly
Albany

Footnotes

1 Gulian Crommelin Verplanck (1780-1870). Author and congressman. Graduated from Columbia in 1801. Admitted to the bar in 1807. Was elected to the New York Assembly in 1820, 1821 and 1822 where his chief interests were educational subjects. In 1824 he was elected to the House of Representatives, and from 1838 to 1841 he was New York State Senator.

2 Clarkson Crolius (1778-1843). Born in New York City. For a long time he was a member of the New York Common Council and for ten years a representative to the State Assembly of which he was elected Speaker in 1825.

3 Walter Bowne (-1846). Grand Sachem of the Tammany Society in 1820. Represented New York in the State Senate for three successive terms. Appointed mayor by the Common Council (1827-1831).

4 Joseph C Yates. Governor of New York from November 6 1822 to November 3 1824.

5 Dr Pascalis is probably referring to his statement of the occurrences during a malignant yellow fever, in the City of New York in the summer and autumnal months of 1819 and of the check given to its progress by the measures adopted by the board of health. [1819].

6 In 1822 there were 1236 deaths from yellow fever in New York City.

7 The New York County Medical Society and the New York State Medical Society were established in 1806.

8 Pharmacists began to receive instruction in New York City in 1829 at the College of Pharmacy of the City of New York a department of Columbia University.

FUNDAMENTALS

I ask that we may recognize that a physician may be a great doctor without doing original and basic laboratory investigation, that such research belongs to the research investigator and practice

to the practitioner. And most of all, I hope that we will go back to the training of medical students clinically by great clinicians to be great clinicians.—H W Haggard, M D

Medical News

The Council Favors Medical Indemnity Insurance Plans

VOLUNTARY medical and surgical insurance against physician's fees received further impetus when the Council of the Medical Society of the State of New York acted favorably on a special committee's report on insurance presented by Dr Herbert H. Bauckus of Buffalo as chairman, on December 15.

The action taken assures wider acceptance by physicians throughout the state of the voluntary insurance principle. It is expected that a number of new organizations will be formed in addition to the three which have already received official authority from the State Department of Social Welfare to operate. These are Medical and Surgical Care of Utica, Western New York Plan of Buffalo, and Medical Expense Fund of New York and Brooklyn.

The purpose of these nonprofit organizations, composed of physicians and laymen, is to provide insurance against doctors' fees up to specified amounts, by the payment of annual charges under plans similar to the 3-cents-a-day hospital insurance system. The plan is approved by the organized medical profession as a substitute for compulsory health insurance under government control.

Compulsion Avoided

"Compulsory health insurance will be unnecessary," stated Dr Peter Irving, secretary and general manager of the state society, "if these projects are successful. Through the voluntary principle, the same low-income groups are to be cared for as has been proposed should be done by compulsory payroll taxation. The basic difference is that persons are not forced to pay against their will and government control is eliminated."

In the absence of statistical information as to the extent of use of the plan, costs cannot be known in advance, Dr Irving explained. "Actuarial knowledge derived from the operation of hospital insurance plans as well as commercial accident and health insurance companies is inapplicable."

The greatest threat to the principle of voluntary insurance, Dr Irving stated, is that the use of services of physicians might far outrun expectations and create ruinous deficits.

Doctors Solve Problem

This problem has been solved, Dr Irving believes, by what amounts to the doctors themselves issuing their insurance.

"If there is a deficit," said Dr Irving, the loss will be prorated among the participating physicians by means of the 'unit system'. Services rendered will not be paid for in full, but credited to the physician on a unit basis. Financial settlements will be made periodically, only to the extent of sums available from the fund.

"If there is a loss, the physician concerned will share it pro rata, if there is a profit it will be added to the surplus for emergencies such as epidemics, used to reduce the member's annual contributions, or to increase the benefits."

The special committee of the society appointed to assist officials of the new organization in solving operation problems consists of Dr William Hale, of Utica, and Dr Walter T. Dannreuther, of New York, in addition to Dr Bauckus.

Quantum Theory of Health and Illness

The New York *Herald Tribune* makes the comment that when the Council of the Medical Society of the State of New York approved the report of its committee on voluntary health insurance it gave tacit approval to what could be accurately described as the quantum theory of health, this latter term including its negative aspect—illness. The committee's report sanctioned a plan under which payments are made during the usual long-continued periods of health to pay for the medical cost of "catastrophic illness." The catastrophic factor for the average individual is usually made up principally of the medical and hospital cost, thanks to the highly advanced state of medical science. These costs are too great to be met out of the miscellaneous item in any weekly or monthly budget, and it is only at rare intervals that there is any necessity for meeting them, but if a portion of the miscellaneous fund is permitted to accumulate it would be adequate to eliminate the catastrophic phase of an illness.

Sudden onset of illness in the midst of health is comparable to the sudden emission of a quantum of energy by an atom and its consequent reduction to a lower energy state. The insurance method of paying the cost of illness could be considered a form of quantum financing. Illness seldom comes to us slowly, or even when it does come by imperceptible stages the crisis usually arrives quickly or, in the language of the physicist, it arrives as a quantum of illness.

Nearly all of our activities are carried on under the quantum theory system. We conserve kindly feeling and generosity throughout the year and when the Christmas season arrives we emit multitudes of quanta of gifts and good will. We then start saving for vacation and, when summer arrives, emit all of our resources in recreation quanta. We work for a week or month and then receive our compensation as a quantum of wages or salary. We preserve a state of sobriety for a long period and then fall off the water wagon into a quantum of indulgence. When we speak in the popular idiom and say "everything comes in bunches" we are expressing the same thought as the scientist who would say the phenomena of life can be described in terms of a quantum theory.

When we recognize the fact that seemingly chaotic experiences of daily existence have an orderly basis that can be described by scientific laws, and when we learn to provide solutions that match our problems, fewer events in our lives will present "catastrophic" aspects. Such scientific planning of our individual lives as is fostered in its sphere by the Medical Society of the State of New York possesses the advantage of retaining for the individual maximum control over his own

affairs. If we sacrifice our individual freedom, concludes the *Herald Tribune*, we face the almost

certain probability of "catastrophic" social, political, and economic ills

County News

Albany County

Dr Philip L. Forster was elected president of the Albany County Medical society, succeeding Dr James S. Lyons, on December 6.

Other officers elected were vice-president, Dr Thomas O. Gamble, secretary, Dr Homer L. Nelms, treasurer, Dr Frances E. Vosburgh, historian, Dr Charles K. Winne, Jr.

Named censors were Dr Lyons, Dr Arthur J. Wallingford, Dr John B. Horner, Dr Morgan O. Barrett, and Dr John J. Phelan.

Delegates to the State Medical society are Dr Stanley E. Alderson, Dr William B. Cornell, and Dr Raymond F. Kircher, with Dr Emerson C. Kelly, Dr Charles A. Perry, and Dr I. J. Murnane as alternates.

Cayuga County

The 134th Annual Dinner Meeting of the Medical Society of the County of Cayuga was held on Thursday, December 14, 1939, in the Osborne Hotel, Auburn, New York.

Business session, with reports of officers for 1939, was held at 6:30 p.m., with dinner for members and their wives at 7:00 p.m.

The speaker of the evening was Milledge L. Bonham, professor of history, Hamilton College, Clinton, New York, who gave a very interesting talk on "American-Canadian Relations."

The following members were elected officers for the year 1940:

W. A. Tucker, M.D., president, E. J. Kemp-ton, M.D., vice-president, S. J. Karpenski, M.D., secretary, R. J. Thomas, M.D., treasurer, board of censors, Drs L. F. O'Neill, Wilfred Sefton, F. L. Okomewski, L. D. Burlington, and M. L. Seccomb, delegate to the 7th District Branch, J. L. Wiley, M.D., alternate to the 7th District Branch, M. O. Parker, M.D., delegate to the State Convention, H. S. Bull, M.D., alternate to the State Convention, W. B. Wilson, M.D.—*Reported by S. J. Karpenski, M.D., Secy*

Chenango County

Dr T. Wood Clarke, of Utica, and Dr Joseph R. Wiseman, of Syracuse, were the speakers at the annual meeting of the Chenango County Medical Society at its 135th annual session at the Norwich Club on December 12.

The program followed a business session at 1:30. The society joined the Norwich Rotary for luncheon at noon.

Erie County

Following an illness of only a few days, Dr Harry M. Weed, Buffalo eye specialist for thirty-five years, died on December 5 in his home 186 Linwood Ave. Death was attributed to coronary thrombosis. Dr Weed was 65. He was professor of ophthalmology in the U. B. Medical School for fifteen years and last June became professor emeritus. He was consultant at the General and Meyer hospitals and attending ophthalmologist at the Millard Fillmore, Children's and St. Mary's Hospitals and the Moses Taylor Hospital in Lackawanna.

During the World War he served in France with the Buffalo medical unit at Base Hospital 23.

Kings County

The scientific program at the meeting of the Medical Society of the County of Kings, on December 19, included these features:

Address "Allergic and Non-Allergic Hypersensitivity as Factors in Industrial Dermatitis," Marion B. Sulzberger, M.D., Manhattan.

Address "Inhalation Allergy: Recent Experiences," Samuel M. Feinberg, M.D., F.A.C.P., Chicago, Ill.

Dr Hyman I. Teperson has been elected president of the East New York Medical Society, one of the oldest organizations of its type in Brooklyn, at the thirtieth annual meeting in the Temple Petach Tikvah, Rochester Ave. and St. John's Place.

Dr Teperson is attending radiologist at the Brooklyn Cancer Institute, Beth El Hospital, Brooklyn Women's Hospital, and other institutions. He is an overseas veteran of the World War, a member of the Officers' Reserve, and a colonel in the Medical Reserve Corps.

Other officers elected were Dr William Levine and Dr Morris Ant, vice-presidents; Dr Max Dannenberg, treasurer; Dr Mortimer M. Kopp, secretary; and Dr Harry Beller, recording secretary.

Dr William Ostrow, 455—75th St., the returning president of the Ridgboro Medical Society, was honored at a testimonial dinner at the Hotel Granada on December 12. Speakers included Peter Sabatino, lawyer, Boris Fingerhood, superintendent of Israel Zion Hospital, and Prof. William MacTavish, Director of the Department of Chemistry of New York University. Dr Ostrow is connected with the Israel Zion and Post Graduate hospitals.

Dr Nathaniel Robinson, who had practiced medicine in Brooklyn for more than fifty years, and had been associated at times with the Cumberland, Carson C. Peck, and Prospect Heights hospitals, died on December 13 at his home, 89 Halsey Street, after an illness of one week.

Monroe County

Dr Albert D. Kaiser was elected president of the Medical Society of the County of Monroe on December 19 as the organization embarked upon its 120th year praised by a state executive leader as second to none in scope and intensity of program.

Dr Kaiser, who succeeds Dr Clarence V. Costello, will serve with Dr C. Stewart Nash, former chairman of the legislative committee, as vice-president and Doctors James J. Rooney and William A. Mac Vay, re-elected treasurer and secretary, respectively.

The doctors, whose proposed plan for medical indemnity insurance is in the offing, heard Dr. Peter Irving, of New York City, secretary and general manager of the State Medical Society,

declare that champions of socialized medicine are "off on the wrong path" with inferences "that we doctors are blocking the advantages of science to the people."

Dr Joseph J Lawrence, of Albany, executive officer of the state society, who shared the platform with Dr Irving and Dr Terry M Townsend, of New York, president of the state society, said he knew of no medical organization in the state so conscientiously engaged at its work as that of Monroe County.

Dr Townsend's address, "The Gift of Giving," was a reminder to physicians that their service in healing is an opportunity, not to be proffered in such a way as to impress patients with greatness of their gift.

The awaited action by the medical group in approving a medical insurance setup was deferred, probably until spring, with the report of Dr E T Wentworth, who pointed out that the investigating committee which he heads is progressing with a view to presenting a plan thoroughly suited to the particular needs of the community. A meeting between the medical committee and a laymen's committee, headed by Marion B Folsom, treasurer of Eastman Kodak Company, is scheduled for January.

A revised constitution was adopted unanimously.

A more general use of the tuberculin skin test in adults as well as children was recommended at a conference of public health officials and representatives of the Monroe County Medical Society and the Tuberculosis and Health Association at Iola Sanatorium, on December 12.

Explaining that the wider use of the tuberculin skin test will enable physicians to discover infection before disease develops and to discover latent diseases where otherwise not suspected, Dr John J Lloyd, committee chairman and vice-president of the Tuberculosis and Health Association, stated that the help of the health association would be sought in the education of parents to have a tuberculin test themselves as well as to have the test given their children.

Seventy Rochester cancer victims joined the growing list of five-year survivors of the disease in 1939, Dr John M Swan of Rochester revealed to New York State leaders in the fight to control cancer, on December 12.

The executive secretary of the state committee of the American Society for the Control of Cancer, at its 15th annual meeting in Powers Hotel, Rochester, asserted

"That should prove to the patient as well as the doctor that cancer can be cured if caught in its early stages."

Ninety Rochesterians are ten-year survivors of cancer, which is seventeen more than last year, Dr Swan said. In all, there are now 360 persons who have lived five or more years since contracting the disease.

Montgomery County

The annual meeting of the Medical Society of the County of Montgomery was held at the Elks Club, Amsterdam, December 13, preceded by a complimentary dinner at 7 o'clock.

Election of officers resulted as follows: president, Dr S L Homrighouse, vice-president, Dr

Julius Schuller, secretary, Dr Roger Conant, treasurer, Dr Leonard M McGugan, censors, Drs William H Seward, William R Rathbun, and R. C. Simpson, delegate to the State Medical Society, Dr H M Hicks, delegate to the Fourth District Branch, Dr E C LaPorte.

The retiring president, Dr L H Finch, reviewed the activities of the society for the past year, which included the postgraduate course given by Wardner D Ayer, M D, of Syracuse, on organic neurology.

At the close of the meeting a motion picture on the "Treatment of Pneumonia" was presented by Dr H M Hicks through the courtesy of the New York State Department of Health on Pneumonia Control.

Nassau County

With a total enrollment of 395, the Nassau County Medical Society finds itself with 175 members who have been in the society less than five years. Nearly all of these members are young men just starting the practice of medicine. This rapid growth has created a number of complications, not the least of which is the difficulty the new men find in getting acquainted with each other and with the older members of the society, and the consequent difficulty of discovering for themselves where and how to secure the assistance of the various governmental agencies whose services are of importance both to the doctor and his patient.

Nassau County presents the unique picture of a populous center very inadequately supplied with hospital facilities, and no dispensary system. The county public hospital, the county welfare department, and the county department of health are all committed to the policy of maximum cooperation with the medical profession, and the Medical Society in turn has repeatedly pledged itself to provide adequate medical service, both preventive and curative, to the recipients of public relief and also to the lower income groups who are unable to pay ordinary medical fees and who in other communities would be considered eligible for free care in dispensaries. In order to acquaint these new men with the governmental facilities available for their assistance, and at the same time to secure their assistance in the Medical Society program of cooperation with the governmental agencies, the society has determined to hold a series of meetings designed particularly for the information and guidance of the new members.

The first of these meetings was held on Tuesday evening, December 19, at the Cathedral House in Garden City with an attendance of 125 members. At this meeting an opportunity was given to the members to ask questions following brief presentation of policy, program, and routine by the superintendents of the two county institutions, that for tuberculosis at Farmingdale, and the public general hospital at Hempstead. State and county health department representatives explained the services available through their organizations, and the chairman of the Professional Advisory Committee of the county welfare department discussed the problems of medical relief.

Because of the interest shown, it has been decided to hold another similar meeting in the near future.—*Reported by J Louis Neff, M.D., Executive Secretary*

New York County

Dr Nathan B Van Etten, of New York, president-elect of the American Medical Association, and three other nationally prominent physicians participated in a symposium on the Wagner National Health Bill at the monthly meeting of the Medical Society of the County of New York at the New York Academy of Medicine, on December 18.

Dr Van Etten and Dr Walter F Donaldson, of Pittsburgh, presented the views of the American Medical Association, which rejected the Wagner Bill in its present form at its annual convention last May in St Louis and recently announced an eight-point platform for guidance in the formulation of a substitute for the Wagner Bill.

Those who spoke in favor of the Wagner Bill were Dr Ernst P Boas, assistant professor of clinical medicine at the College of Physicians and Surgeons, Columbia University, and Dr Robert B Osgood of Boston, professor emeritus of orthopedic surgery at the Harvard Medical School. Drs Boas and Osgood are members of the Committee of Physicians that came out in 1937 in favor of a national health policy that served as the basis for the Wagner Bill.

Onondaga County

Dr Burton C Doust was elected president at the 133rd annual meeting of the Onondaga County Medical Society on December 5 at the University Club of Syracuse. He succeeds Dr Leon E Sutton. Other officers are Dr Leo E Gibson, vice-president, Dr Dwight V Needham, secretary, and Dr A Carl Hofmann, treasurer.

R Marcus Dick, executive secretary, will continue in that position for another year. The office has been moved from the Starrett-Syracuse building to 308 Medical Arts building.

Dr Orren D Chapman and Dr John C M Brust were named censors for three years.

Dr John J Buettner was elected for a three-year term as delegate to the state society, with Dr Sutton as alternate.

Dr Ellery G Allen, Dr Raymond J Pieri, Dr Carl J Geiger, and Dr Floyd R. Parker were elected for one-year terms as delegates to the Fifth District Branch of the New York State Medical Society.

Oswego County

Dr H M Wallace of Oswego was elected president of the Oswego County Medical Society at the annual meeting on December 14. Dinner preceded the business session.

Other officers named are as follows: vice-president, Dr Edward F Fox, Fulton, and secretary and treasurer, Dr Francis L Carroll, Oswego. Dr Kent W Jarvis, Oswego, was named delegate to the state society, Dr S D Keller, Fulton, censor for three years.

Rensselaer County

Dr Charles W Hamm was elected president of the Rensselaer County Medical Society at the annual meeting at the Troy Health Center on December 12.

Other officers chosen include

Dr John O Sibbald, vice-president, Dr Leo S Weinstein, secretary, Dr John F Russell, treasurer, Dr William Trotter and Dr Charles

H Sproat, censors, Dr John D Carroll and Dr Stephen H Curtis, delegates and Dr Clement J Handron and Dr George F Reed, alternates.

The new officers were installed at the society's annual dinner at the Hendrick Hudson on December 13.

Dinner speakers included Dr Sarah M Jordan, head of the gastroenterology department, Lahey Clinic, Boston, Mass., who spoke on "Colitis," and Dr Terry M Townsend, of New York City, president of the Medical Society of the State of New York, who spoke on "State Affairs."

The state president, referring to moves which have been made toward "regimentation" of the profession, saw in a united front the best protection of the practice of medicine against political control.

Dr Shields delivered the address of welcome to the approximately 100 county physicians attending. At the close of the speaking program, Dr Shields turned over the gavel to the newly elected president of the county society, Dr Charles W Hamm, and the new officers for the coming year were inducted.

Music was furnished by a trio directed by Irving Rosenholtz, with Bea Kane, vocalist.

Richmond County

Dr Herbert A Cochrane, of 2 St. Mark's Place, New Brighton, was elected president of the Richmond County Medical Society at a meeting in the Richmond Health Center, 51 Stuyvesant Place, St George, on December 13. He succeeds Dr Frederick M. Schwerd of Princes Bay, president the past two years.

Dr Cochrane had been vice-president the past two years. Dr H Lynn Halbert was elected to Dr Cochrane's former post. Dr George W McCormick was elected secretary, replacing Dr John K. Lucey, secretary the past two years. Dr Curtis J Becker was elected treasurer for a third term.

Following the election the members heard a talk on "Brain Tumors," delivered by Dr Samuel Reback, attending neurologist at Staten Island Hospital and associate neurologist at the New York Neurological Institute, Manhattan.

A medical center for South Shore physicians will be erected in Great Kills by Dr Frederick M. Schwerd, retiring president of the Richmond County Medical Society. Plans for the building, which will cost \$17,000, have been filed with the Department of Housing and Buildings at Borough Hall.

Dr Walker Washington, retired physician and a collateral descendant of George Washington died on December 10 at his home, 127 Main Street, Tottenville, S I., after a long illness. He was seventy-nine years old.

Dr Washington was a founder and former president of the Tottenville National Bank and a former president of the Richmond County Medical Society. In the fifty-two years he practiced medicine on Staten Island before retiring two years ago he attended at the births of more than 2,500 infants and, in the last twenty-five years of his practice, was said never to have lost a mother. He also was a specialist in diseases of the lungs and heart.

Rockland County

Dr Russell E Blaisdell, superintendent of Rockland State Hospital, was elected president of the Medical Society of Rockland County to succeed Dr Pomerantz of Spring Valley, at the annual meeting on December 6, in Nyack. The other officers elected were Dr M. J Sullivan of Haverstraw, vice-president, Dr Miltmore of

Nyack, re-elected treasurer, and Dr William J Ryan of Summit Park, re-elected secretary

Dr John Sengstacken, one of the deans of Rockland county physicians, recently completed his fiftieth year of medical practice in Stony Point and soon will have an equally long record as health officer of the town of that name—says *Health News*

A BOOK FOR YOUNG FOLKS ON "CATCHING" DISEASES

In order to secure greater public cooperation for the control of "catching" diseases, the Public Health Service has issued a new twenty-five cent booklet entitled, *Communicable Diseases*

"If people understand the nature of disease, if they understand why certain control measures are necessary, they will cooperate," Dr A M Stimson, Medical Director, U S Public Health Service and author of the book, states in his introduction.

"If people understand, they will obey reasonable rules and regulations. They will go to their doctors when symptoms appear and shun the quack and the patent medicine vendor," Dr Stimson concludes

This 124-page booklet, distributed by the Government Printing Office, is intended as a source of dependable information primarily for students in high schools and junior colleges and discusses about forty infectious diseases which are considered "the most important for people

living in America at the present time to know something about."

Included in the booklet are essential facts on such diseases as chicken pox, common cold, diphtheria, food infections and food poisonings, measles, gonorrhea, infantile paralysis, influenza, mumps, pneumonia, septic sore throat, and whooping cough. This compact little volume also contains a glossary explaining the different terms and a section of suggestions for teachers.

In a preface to the booklet, Dr J F Rogers, Consultant in Hygiene, U S Office of Education, declares that "knowledge is our most potent agent in bringing about the prevention of disease and the promotion of health"

Many diseases are communicable, but, fortunately, information concerning those diseases is also communicable, observes Dr Rogers, who points out that, "If we would put into practice all the knowledge furnished in this booklet, the number of the sick and of premature deaths would be greatly reduced"

Hospital News

A Hospital Code of Employee Relations

THE right of voluntary hospitals to discharge employees "without intimidation or interference when, in the judgment of the management, such course is in the interest of the welfare of patients and efficiency of the institution," is set forth in a code of employee relations adopted by members of the Greater New York Hospital Association.

"The interest of public safety and public health requires that discipline be observed by every hospital employee," the code declares. "The right of the sick person to uninterrupted, skillful and efficient care precludes any right of employees to obstruct or impede hospital service. Any organized effort to interfere with hospital service must be regarded as an act of hostility to the common good."

The hospital administrators agree that employees should be free to join any lawful organization but that employment should not be made dependent on membership or nonmembership in any group. According to the code, workers are entitled to receive wages "comparable with those which prevail in the community for similar type of work done and commensurate with the financial resources of the hospital."

"The hours of work," it is declared, "should not exceed a reasonable maximum per day or week, but it should be recognized that in some departments of a hospital emergent situations may require longer periods of work. It should be recognized further that the peculiar nature of hospital work makes extremely difficult the adherence to such time schedules as may obtain in industry."

John F. McCormack, superintendent of Presbyterian Hospital, is president of the association.

"Frozen Sleep" at Welfare Island

DR S S GOLDWATER, Commissioner of Hospitals, New York City, announces that cryomotherapy, popularly known as the hibernation or frozen sleep method for the treatment of cancer, will be undertaken at City Hospital on Welfare Island. The installation of a special chamber at City Hospital has been made possible by a donation of about \$4,000 from Mr and Mrs Walter C. Baker of 555 Park Avenue, New York. Mr Baker is a trust officer of the Guaranty Trust Co., a member of the Manhattan Eye, Ear, Nose, and Throat Hospital, and a life trustee of Union College.

Cryomotherapy has been employed as a palliative in cancer treatment at a number of institutions throughout the country. The most extensive experiments have been carried on at Temple Hospital in Philadelphia, where more than 80 cases have been treated with promising results. Tissue studies made at Temple Hospital are reported to show definite regression in growth, with disappearance of cancer cells from local lesions. Parallel studies were more recently undertaken in New York City at Lenox Hill Hospital, from which institution encouraging reports have been received.

The treatment at City Hospital will be under the direction of a staff committee consisting of Dr W. Laurence Whittemore, visiting physician, Dr Paul K. Sauer, visiting surgeon, and Dr James R. Lisa, pathologist. Dr Sauer is associated also with the work at Lenox Hill Hospital.

The views of the City Hospital Staff committee have been summed up in a report as follows:

"The thought of the chemists, pathologists, and biologists regarding cryomotherapy is that there are definite changes in the histological and biochemical structure of the cellular membrane, that apparently indicate a type of change known as crystalloid precipitation. Moreover, the protoplasm of the cell also is modified. These retrograde metamorphoses are then absorbed and replacement takes place by normal connective and fibrous tissue, somewhat on the type of scarring effect."

"These evidences are clearly discernible in cases studied by competent authorities. A demonstration of slides and biopsy specimens at Temple University presented evidences of improvement in patients cared for under cryomotherapy."

"We are of the opinion that if not of curative value, at least this method of treatment has much to offer as a palliative therapy in relieving pain and in offering a longer and more useful existence to those afflicted with cancer."

Newsy Notes

MERGER is announced of the Herman Knapp Memorial Eye Hospital, 500 West 57th Street, New York City, with the Columbia University and Columbia-Presbyterian Medical Center. Following closing of the eye hospital, January 1, after 70 years' operation, its clinical and teaching activities were taken over by the Presbyterian Hospital and the Vanderbilt Clinic.

The Hospital for the Ruptured and Crippled in New York City has been celebrating its seventy fifth anniversary with a week of receptions, scientific meetings, a dinner at the University Club, and a dance at the Waldorf-Astoria Hotel. A 157-page history of the hospital, by Dr Fenwick Beekman, has been issued.

A proposal to increase the pay of 784 interns in the New York City hospitals from \$15 a month to \$35 was defeated in the Board of Estimate on November 2 after a sharp exchange of personalities.

Overcrowding in institutions for the mentally ill, such as Utica State Hospital, isn't caused by the "dizzy pace" of modern life.

Rather, in the opinion of Dr Willis E. Merriam, new superintendent of the hospital, in increasing population of these institutions is due to the economic situation, plus increased cooperation from social service organizations.

Utica State Hospital, with a nominal capacity

of 1,552, now carries 2,073 patients on its books, with 1,720 actually sheltered there. The other 353 are on parole or in boarding homes.

Within the last few years there has been a tendency by social service organizations to "sell" the idea of institutional care to families which might have been burdened by a member with mental sickness. A greater public confidence has developed in state hospitals, Dr Merriman pointed out.

Clinics to discover persons needing hospitalization for mental illness are conducted every Friday at Utica Dispensary. In addition, a member of the local hospital's medical staff conducts clinics every two months in Schenectady, Amsterdam, Saratoga, and Johnstown.

• •

A child should never be sent to the hospital without being told where he is going, Mary L. Poole, Philadelphia, warns in *Hygia*, The Health Magazine.

On the child's adjustment to the hospital partly depends his ability to be benefited by the care he receives, she points out. When the idea of hospitalization is not introduced in a straightforward manner, much psychologic harm may be done. The child may have a deep sense of insecurity and a feeling of distrust toward his parents, and on future occasions when hospitalization is necessary he may relive his original terror.

• •

A new method of detecting diseases of the lungs, notably tuberculosis and silicosis, is being employed at Memorial Hospital in Albany by means of a common photographic utensil, the light meter, and is described in the Albany newspapers.

Proponents of the technique have rechristened the light-measuring device "the pneumometer."

Development of the method is credited to the researchers of the John B. Pierce Foundation in New York, which is undertaking extensive study of the silicosis problem.

The discovery is ranked in importance with the x-ray itself as a means of detecting lung disorders.

The pneumometer method of diagnosis measures the amount of light seeping through x-rays of lungs, mounted on illuminating boxes. Measurements, in units of light, are made at five points: the heart, base of lungs, middle part of lungs, apex of lungs, and windpipe.

Measurements are recorded on a graph, and lines between the points connected. Should the lines form a U-shape, lungs usually are normal. Should a W-shape be the result, silicosis is indicated. Where tuberculosis is present a shape similar to the square root sign is formed. If cancer is present a double V-shape appears.

Value of the method is based on the logic that the eye is more sensitive than the ear, and film even more sensitive than the eye.

Improvements

HOSPITAL needs of the boroughs of Brooklyn and Queens, often described by Mayor La Guardia as outranking more spectacular public

improvements, are estimated at \$40,761,000 by Commissioner S. S. Goldwater in his annual report for 1938.

"New institutions which ought to be erected between now and 1945," he says, "would involve \$14,850,000 in Brooklyn and \$6,650,000 in Queens." The former would provide 1,300 additional beds, and the latter, 500 beds. Dispensary services could account profitably for \$2,002,000 in the older community and \$270,000 in the younger. Miscellaneous expenditures for better facilities are outlined by Dr Goldwater at \$14,088,500 in Brooklyn and \$2,800,000 in Queens.

•

Shampan & Shampan, architects, are preparing plans for the Boro Park General Hospital for rebuilding the hospital buildings, located on the southwest corner of Fifteenth Avenue and Forty-fifth Street, Brooklyn. The main hospital is now a two-story fireproof building, and will be extended two stories in height. The exteriors of the buildings are being redesigned in modern style introducing glass blocks on the exterior and for interior partitions. It is estimated that the work will cost about \$100,000.

The former St. Cecilia Hospital for Women at 434 Humboldt Street, Brooklyn, which was closed after the death of the Rt. Rev. Mons. Edward J. McGolrick has been reopened under the supervision and management of St. Catherine's Hospital, according to announcement by the Rev. Paul J. Faustmann of St. Catherine's Hospital.

The old St. Cecilia Hospital will be known as St. Catherine's Maternity Hospital, Monsignor McGolrick Memorial Building.

•

A proposal to establish a community hospital at Woodmere, L. I., to serve the area from Idwood to Hewlett has been broached by the Woodmere Exchange Club. Dr. E. Wallace Small, president of the club, has appointed Dr. Curt B. Hardt as chairman of a community hospital committee to promote the project.

Work has started on the three-story addition to the Mount Vernon Hospital, to cost \$126,600.

•

Work on the new \$300,000 wing of the South Nassau Communities hospital, Oceanside, has been begun. The hospital will be doubled in size on completion of the project.

The construction work will be done by John J. Dixon Company, Inc., of Roosevelt, for \$215,000.

Equipment of the new wing will cost \$45,000, furnishings will amount to \$25,000, and other expenditures will total \$15,000. The wing, which when completed will give the hospital a 'Y' shape, will have fifty-eight beds, three operating rooms, two delivery rooms, a nursery, laboratory, and increased facilities for doctors, nurses, executive offices, laundry, and boiler room.

The bulk of the cost of the improvement will be paid by means of a 10-year \$200,000 mortgage.

Hospital News

A Hospital Code of Employee Relations

THE right of voluntary hospitals to discharge employees "without intimidation or interference when, in the judgment of the management, such course is in the interest of the welfare of patients and efficiency of the institution," is set forth in a code of employee relations adopted by members of the Greater New York Hospital Association.

"The interest of public safety and public health requires that discipline be observed by every hospital employee," the code declares. "The right of the sick person to uninterrupted, skillful and efficient care precludes any right of employees to obstruct or impede hospital service. Any organized effort to interfere with hospital service must be regarded as an act of hostility to the common good."

The hospital administrators agree that employees should be free to join any lawful organization but that employment should not be made dependent on membership or nonmembership in any group. According to the code, workers are entitled to receive wages "comparable with those which prevail in the community for similar type of work done and commensurate with the financial resources of the hospital."

"The hours of work," it is declared, "should not exceed a reasonable maximum per day or week, but it should be recognized that in some departments of a hospital emergent situations may require longer periods of work. It should be recognized further that the peculiar nature of hospital work makes extremely difficult the adherence to such time schedules as may obtain in industry."

John F. McCormack, superintendent of Presbyterian Hospital, is president of the association.

"Frozen Sleep" at Welfare Island

DR. S. S. GOLDWATER, Commissioner of Hospitals, New York City, announces that cryomotherapy, popularly known as the hibernation or frozen sleep method for the treatment of cancer, will be undertaken at City Hospital on Welfare Island. The installation of a special chamber at City Hospital has been made possible by a donation of about \$4,000 from Mr. and Mrs. Walter C. Baker of 555 Park Avenue, New York. Mr. Baker is a trust officer of the Guaranty Trust Co., a member of the Manhattan Eye, Ear, Nose, and Throat Hospital, and a life trustee of Union College.

Cryomotherapy has been employed as a palliative in cancer treatment at a number of institutions throughout the country. The most extensive experiments have been carried on at Temple Hospital in Philadelphia, where more than 80 cases have been treated with promising results. Tissue studies made at Temple Hospital are reported to show definite regression in growth, with disappearance of cancer cells from local lesions. Parallel studies were more recently undertaken in New York City at Lenox Hill Hospital, from which institution encouraging reports have been received.

The treatment at City Hospital will be under the direction of a staff committee consisting of Dr. W. Laurence Whittemore, visiting physician, Dr. Paul K. Sauer, visiting surgeon, and Dr. James R. Lisa, pathologist. Dr. Sauer is associated also with the work at Lenox Hill Hospital.

The views of the City Hospital Staff committee have been summed up in a report as follows:

"The thought of the chemists, pathologists, and biologists regarding cryomotherapy is that there are definite changes in the histological and biochemical structure of the cellular membrane, that apparently indicate a type of change known as crystalloid precipitation. Moreover, the protoplasm of the cell also is modified. These retrograde metamorphoses are then absorbed and replacement takes place by normal connective and fibrous tissue, somewhat on the type of scarring effect.

"These evidences are clearly discernible in cases studied by competent authorities. A demonstration of slides and biopsy specimens at Temple University presented evidences of improvement in patients cared for under cryomotherapy.

"We are of the opinion that if not of curative value, at least this method of treatment has much to offer as a palliative therapy in relieving pain and in offering a longer and more useful existence to those afflicted with cancer."

Newsy Notes

MERGER is announced of the Herman Knapp Memorial Eye Hospital, 500 West 57th Street, New York City, with the Columbia University and Columbia-Presbyterian Medical Center. Following closing of the eye hospital, January 1, after 70 years' operation, its clinical and teaching activities were taken over by the Presbyterian Hospital and the Vanderbilt Clinic.

The Hospital for the Ruptured and Crippled in New York City has been celebrating its seventy-fifth anniversary with a week of receptions, scientific meetings, a dinner at the University Club, and a dance at the Waldorf-Astoria Hotel. A 157-page history of the hospital, by Dr. Fenwick Beekman, has been issued.

A proposal to increase the pay of 784 interns in the New York City hospitals from \$15 a month to \$35 was defeated in the Board of Estimate on November 2 after a sharp exchange of personalities.

Overcrowding in institutions for the mentally ill, such as Utica State Hospital, isn't caused by the "dizzy pace" of modern life.

Rather, in the opinion of Dr. Willis E. Merriam, new superintendent of the hospital, in increasing population of these institutions is due to the economic situation, plus increased cooperation from social service organizations.

Utica State Hospital, with a nominal capacity

the writer set forth his findings. We have spent the interval between editions presenting a little new data and a great mass of speculation.

The seventh edition is certainly radically different in style and substance from those of the past, but it is no less authoritative. The first few pages seem over-philosophical until the reader suddenly realizes that he is intensely interested in the really basic aspects without which no intelligent understanding of the subject can be reached. Comparative anatomy and physiology are stressed in some detail, and lead up to the human anatomic and physiologic considerations on which the pathologic conditions are based.

As the author says it is not really possible to bring "Worth" up to date. It is a milestone, and miles do not grow longer. A new book has actually been written on the framework of the old, but the substance in the new model is as different as was anatomy and particularly the physiology of thirty-five years ago. It is absolutely essential that a consideration of the subject be modern, and those who have not grown with the times will not like this new edition.

The ground work for the book is laid in the first 100 pages, the pathologic aspects viewed in a modern light come next, and the classical development of the subject follows. It is a fine textbook, but the beginner would do better by reading less elaborate works.

The pages on surgery of squint interested the reviewer least, and it seems unfortunate that so fine a work is unaccompanied by references to the literature.

JOHN N EVANS

Oh, Doctor! My Feet! By Dudley J. Morton, M.D. Duodecimo of 116 pages, illustrated New York, D. Appleton-Century Co., 1939 Cloth, \$1.50

"A man convinced against his will is of the same opinion still, a woman convinced against her will is neither convinced nor is she still."

There is no metatarsal arch.

The supposed beautiful long second toe is a congenital malformation.

Nature intended a normal foot to have the second metatarsal extend only as far as the first. The first metatarsal is designed to and should support more than twice the weight of any of those other four. A long second metatarsal of necessity will bear more than its share of weight, a job beyond its capacity. This extra load is taken from the large first, a situation Dr. Morton calls a "lazy first metatarsal." Most of foot "stram" and later formation of the usual callous below the second metatarsal head are directly due to this excess burden that this bone must bear. An x-ray of the metatarsals proves this contention. For relief, a pad is placed on an insole under the "lazy first metatarsal" to give it the share of weight bearing it was intended to carry, not under the second behind the callous or point of tenderness as has been done for years.

The family doctor is the logical man to care for the majority of foot ailments. This excellent book, written for the layman has had unusual response from the newspapers and lay magazines, and will, we hope, have a wide distribution.

It will be a direct factor in forcing foot care to the group it rightfully belongs, the medical profession. When enough patients request and expect their family doctor to care for their feet, then the medical profession will make an effort to consider this all too common ailment a part of medical care.

The book is well written, the subject is presented in an unusual manner, and is completely convincing.

PAUL C. ESCHWEILER

Failure of the Circulation. By Tinsley R. Harrison, M.D. Second edition. Octavo of 502 pages, illustrated. Baltimore, Williams & Wilkins Co., 1939. Cloth, \$4.50.

In his second edition Harrison stresses the importance of the clinical recognition of imminent congestive failure, its treatment when progressing to more severe levels, and the treatment of angina pectoris (sans coronary occlusion). It is the author's hope that the clinical Heberden syndrome has achieved such definition that there should be no further beclouding of its character. To this end, physiologic investigations have contributed valuable observations, and he unqualifiedly accepts the Keefer and Resnik hypothesis advanced in 1928 that it is due to "relative anoxemia of the myocardium."

Harrison has substituted the terms "forward failure" (inadequate blood supply to the tissues) and "backward failure" (congestive failure) for the terms used in his first edition, to wit, "hypokinetic syndrome" and "dyskinetic failure" respectively, which while etymologically sound, rather taxed one's quick everyday clinical grasp. For this change we are grateful.

The volume abounds in clinical facts, diagnostic analysis, and sound therapy. The author's style is pleasing, and the reader's eye moves easily through the text. There is no questioning the soundness and authority that characterize the volume, the references are thorough, and quotations from the literature are extensive and illuminating.

FRANK B. CROSS

Textbook of General Surgery. By Warren H. Cole, M.D., and Robert Elman, M.D. Second edition. Octavo of 1,031 pages, illustrated. New York, D. Appleton-Century Co., 1939. Cloth, \$8.00.

This single volume comprises 994 pages to which are added a comprehensive index of authors and subjects. Conciseness in giving a systematic survey of the whole field of surgery is kept in mind. The material is divided into thirty chapters. Extensive descriptions of operations are not given, but the principles involved in various operative procedures are stated. Detailed consideration of several specialties are eliminated, but those features with which the general surgeon should be familiar are included. The physiologic point of view and the pathogenesis are emphasized in order to better understand treatment. The book is richly supplied with illustrations and photomicrographs, which add greatly to the value of the text. Recent advances in surgery, particularly in the field of

REVIEWED

Medicolegal Phases of Occupational Diseases
An Outline of Theory and Practice By C O Sappington, M D Octavo of 405 pages, illustrated Chicago, Industrial Health Book Co, 1939 Cloth, \$2 75

The author endeavors to include in a small book the subjects of Industrial Hygiene, Statistics, Diseases of Occupation, Workmen's Compensation Law, Casualty Insurance, and Law Many large volumes have been written on these subjects, and small works on each one are numerous, therefore, we must appreciate the enormous task attempted by the author

The author truly states that "the monograph cannot in any way be considered a textbook on occupational diseases," and further remarks that "those who may assume that the material in this small volume will provide the easy solution of their difficulties will be doomed to keen disappointment."

The author has secured his material from numerous governmental publications as well as individual writings He includes illustrations of apparatus used in analysis The treatment of the different subjects is brief, in some instances a line and one-half is used to describe one of the industrial intoxications

A small and rather incomplete bibliography is included after the subjects, there is, however, a very complete index.

The author is to be commended for his laudable attempt, and while it is just another book in the field of industrial hygiene and workmen's compensation, it may prove useful to those who desire a small concise handbook on these subjects

C T GRAHAM-ROGERS

Pye's Surgical Handicraft A Manual of Surgical Manipulations, Minor Surgery, and Other Matters Connected with the Work of House Surgeons and of Surgical Dressers Edited by Hamilton Bailey, F R C S Eleventh edition Octavo of 512 pages, illustrated Baltimore, Williams & Wilkins Co, 1939 Cloth, \$6 00

This is the eleventh edition of a book which first appeared in 1884, with a tenth edition in 1931 The subtitle tells its plan and scope "A Manual of Surgical Manipulations, Minor Surgery, and Other Matters Connected with the Work of House Surgeons and of Surgical Dressers" As might be expected, it contains many practical demonstrations and suggestions for training the intern. As in a previous edition, about 100 pages are devoted to the treatment of fractures All books of this type are, of course, of the nature of a compend, with the inherent advantages and disadvantages of compends One is impressed by the English accent and atmosphere A book which is published with an

appeal to the American intern in 1939 should have at least some index reference to such well-known items as the Wangenstein Drainage, Russell Traction, and the Miller-Abbott Tube.

J RAPHAEL

Endocrinology in Modern Practice By William Wolf, M D Second edition. Octavo of 1,077 pages, illustrated Philadelphia, W B Saunders Co, 1939 Cloth, \$10

Dr Wolf's widely advertised *Endocrinology* has appeared in its second edition. The book is revised in an attempt to bring it up to date. It is a well-written, easily readable book which will appeal, in all likelihood, to many general practitioners

The criticism directed against the first edition still holds there is no evidence that the author speaks with authority on the subject. Neither research work nor clinical contributions of the author are known, and most of the illustrations of the book are reproduced from other publications or are due to the courtesy of other physicians Thus, the text is not upheld by personal authority, and is not even supported by adequate references or bibliography Hence, this volume must be classed as a compilation by a diligent, but not always discriminating reader of endocrine literature, it is utterly lacking in individual concepts, and both classification of endocrine syndromes and their interpretation are strictly conventional Almost one half of the book is devoted to the endocrine aspects of "Non-Endocrine" diseases, discussing manifestations noted on the various organs of the body This section includes some valuable points which, however, are submerged in a welter of irrelevant material Additional chapters deal with interpretation of laboratory findings and procedures, in addition to a rather complete enumeration of the commercially available endocrine preparations

MEYER A. HALPERIN

Worth's Squint or the Binocular Reflexes and the Treatment of Strabismus Seventh edition by F Bernard Chavasse, M A Octavo of 688 pages, illustrated Philadelphia, P Blakiston's Son & Co, 1939 Cloth, \$8 00

We have waited nearly a score of years for the present revision of Worth During that time we have fed upon, and for the most part assimilated the story of squint that Worth set before us, and we have seen the literature grow by leaps and bounds The reviewer has long felt the need of a monograph which would make accessible the accumulated evidence of these years He has looked forward in the hope of finding new tools

Perhaps the older editions of Worth are best remembered for the simple manner in which

the writer set forth his findings. We have spent the interval between editions presenting a little new data and a great mass of speculation.

The seventh edition is certainly radically different in style and substance from those of the past, but it is no less authoritative. The first few pages seem over-philosophical until the reader suddenly realizes that he is intensely interested in the really basic aspects without which no intelligent understanding of the subject can be reached. Comparative anatomy and physiology are stressed in some detail, and lead up to the human anatomic and physiologic considerations on which the pathologic conditions are based.

As the author says, it is not really possible to bring "Worth" up to date. It is a milestone, and miles do not grow longer. A new book has actually been written on the framework of the old, but the substance in the new model is as different as was anatomy and particularly the physiology of thirty-five years ago. It is absolutely essential that a consideration of the subject be modern, and those who have not grown with the times will not like this new edition.

The ground work for the book is laid in the first 100 pages, the pathologic aspects viewed in a modern light come next, and the classical development of the subject follows. It is a fine textbook, but the beginner would do better by reading less elaborate works.

The pages on surgery of squint interested the reviewer least, and it seems unfortunate that so fine a work is unaccompanied by references to the literature.

JOHN N EVANS

Oh, Doctor! My Feet! By Dudley J. Morton, M.D. Duodecimo of 116 pages, illustrated. New York, D. Appleton-Century Co., 1939. Cloth, \$1.50.

"A man convinced against his will is of the same opinion still, a woman convinced against her will is neither convinced nor is she still."

There is no metatarsal arch.

The supposed beautiful long second toe is a congenital malformation.

Nature intended a normal foot to have the second metatarsal extend only as far as the first. The first metatarsal is designed to and should support more than twice the weight of any of those other four. A long second metatarsal of necessity will bear more than its share of weight, a job beyond its capacity. This extra load is taken from the large first, a situation Dr. Morton calls a "lazy first metatarsal." Most of foot "strain" and later formation of the usual callous below the second metatarsal head are directly due to this excess burden that this bone must bear. An x-ray of the metatarsals proves this contention. For relief, a pad is placed on an insole under the "lazy first metatarsal" to give it the share of weight bearing it was intended to carry, not under the second behind the callous or point of tenderness as has been done for years.

The family doctor is the logical man to care for the majority of foot ailments. This excellent book, written for the layman has had unusual response from the newspapers and lay magazines, and will, we hope, have a wide distribution.

It will be a direct factor in forcing foot care to the group it rightfully belongs, the medical profession. When enough patients request and expect their family doctor to care for their feet, then the medical profession will make an effort to consider this all too common ailment a part of medical care.

The book is well written, the subject is presented in an unusual manner, and is completely convincing.

PAUL C. ESCHWEILER

Failure of the Circulation. By Tinsley R. Harrison, M.D. Second edition. Octavo of 502 pages, illustrated. Baltimore, Williams & Wilkins Co., 1939. Cloth, \$4.50.

In his second edition Harrison stresses the importance of the clinical recognition of imminent congestive failure, its treatment when progressing to more severe levels, and the treatment of angina pectoris (*sans* coronary occlusion). It is the author's hope that the clinical Heberden syndrome has achieved such definition that there should be no further beclouding of its character. To this end, physiologic investigations have contributed valuable observations, and he unqualifiedly accepts the Keefer and Resnik hypothesis advanced in 1928 that it is due to "relative anoxemia of the myocardium."

Harrison has substituted the terms "forward failure" (inadequate blood supply to the tissues) and "backward failure" (congestive failure) for the terms used in his first edition, to wit, "hypokinetic syndrome" and "dyskinetic failure" respectively, which while etymologically sound, rather taxed one's quick everyday clinical grasp. For this change we are grateful.

The volume abounds in clinical facts, diagnostic analysis, and sound therapy. The author's style is pleasing, and the reader's eye moves easily through the text. There is no questioning the soundness and authority that characterize the volume, the references are thorough, and quotations from the literature are extensive and illuminating.

FRANK B. CROSS

Textbook of General Surgery. By Warren H. Cole, M.D., and Robert Elman, M.D. Second edition. Octavo of 1,031 pages, illustrated. New York, D. Appleton-Century Co., 1939. Cloth, \$8.00.

This single volume comprises 994 pages to which are added a comprehensive index of authors and subjects. Conciseness in giving a systematic survey of the whole field of surgery is kept in mind. The material is divided into thirty chapters. Extensive descriptions of operations are not given, but the principles involved in various operative procedures are stated. Detailed consideration of several specialties are eliminated, but those features with which the general surgeon should be familiar are included. The physiologic point of view and the pathogenesis are emphasized in order to better understand treatment. The book is richly supplied with illustrations and photomicrographs, which add greatly to the value of the text. Recent advances in surgery, particularly in the field of

Books

Books for review should be sent to the Book Review Department at 1313 Bedford Avenue, Brooklyn, N Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers.

REVIEWED

Medicolegal Phases of Occupational Diseases. An Outline of Theory and Practice. By C O Sappington, M D. Octavo of 405 pages, illustrated. Chicago, Industrial Health Book Co, 1939. Cloth, \$2.75.

The author endeavors to include in a small book the subjects of Industrial Hygiene, Statistics, Diseases of Occupation, Workmen's Compensation Law, Casualty Insurance, and Law. Many large volumes have been written on these subjects, and small works on each one are numerous, therefore, we must appreciate the enormous task attempted by the author.

The author truly states that "the monograph cannot in any way be considered a textbook on occupational diseases," and further remarks that "those who may assume that the material in this small volume will provide the easy solution of their difficulties will be doomed to keen disappointment."

The author has secured his material from numerous governmental publications as well as individual writings. He includes illustrations of apparatus used in air analysis. The treatment of the different subjects is brief, in some instances a line and one-half is used to describe one of the industrial intoxications.

A small and rather incomplete bibliography is included after the subjects, there is, however, a very complete index.

The author is to be commended for his laudable attempt, and while it is just another book in the field of industrial hygiene and workmen's compensation, it may prove useful to those who desire a small concise handbook on these subjects.

C T GRAHAM-ROGERS

Pye's Surgical Handicraft. A Manual of Surgical Manipulations, Minor Surgery, and Other Matters Connected with the Work of House Surgeons and of Surgical Dressers. Edited by Hamilton Bailey, F.R.C.S. Eleventh edition. Octavo of 512 pages, illustrated. Baltimore, Williams & Wilkins Co, 1939. Cloth, \$6.00.

This is the eleventh edition of a book which first appeared in 1884, with a tenth edition in 1931. The subtitle tells its plan and scope. "A Manual of Surgical Manipulations, Minor Surgery, and Other Matters Connected with the Work of House Surgeons and of Surgical Dressers." As might be expected, it contains many practical demonstrations and suggestions for training the intern. As in a previous edition, about 100 pages are devoted to the treatment of fractures. All books of this type are, of course, of the nature of a compend, with the inherent advantages and disadvantages of compends. One is impressed by the English accent and atmosphere. A book which is published with an

appeal to the American intern in 1939 should have at least some index reference to such well-known items as the Wangenstein Drainage, Russell Traction, and the Miller-Abbott Tube.

J RAPHAEL

Endocrinology in Modern Practice. By William Wolf, M D. Second edition. Octavo of 1,077 pages, illustrated. Philadelphia, W B Saunders Co, 1939. Cloth, \$10.

Dr Wolf's widely advertised *Endocrinology* has appeared in its second edition. The book is revised in an attempt to bring it up to date. It is a well-written, easily readable book which will appeal, in all likelihood, to many general practitioners.

The criticism directed against the first edition still holds. There is no evidence that the author speaks with authority on the subject. Neither research work nor clinical contributions of the author are known, and most of the illustrations of the book are reproduced from other publications or are due to the courtesy of other physicians. Thus, the text is not upheld by personal authority, and is not even supported by adequate references or bibliography. Hence, this volume must be classed as a compilation by a diligent, but not always discriminating reader of endocrine literature, it is utterly lacking in individual concepts, and both classification of endocrine syndromes and their interpretation are strictly conventional. Almost one half of the book is devoted to the endocrine aspects of "Non-Endocrine" diseases, discussing manifestations noted on the various organs of the body. This section includes some valuable points which, however, are submerged in a welter of irrelevant material. Additional chapters deal with interpretation of laboratory findings and procedures, in addition to a rather complete enumeration of the commercially available endocrine preparations.

MEYER A HALPERIN

Worth's Squint or the Binocular Reflexes and the Treatment of Strabismus. Seventh edition by F Bernard Chavasse, M A. Octavo of 688 pages, illustrated. Philadelphia, P Blakiston's Son & Co, 1939. Cloth, \$8.00.

We have waited nearly a score of years for the present revision of Worth. During that time we have fed upon, and for the most part assimilated the story of squint that Worth set before us, and we have seen the literature grow by leaps and bounds. According to Need

Unless federal aid for medical services is to be a form of glorified political patronage, it seems obvious that it should be distributed on the sole basis of need. One of the grave flaws in the Wagner National Health Bill was its adherence to the principle that the states must match federal grants. With this requirement in force, the richest states, which have least need of help, obtain the most money from Washington. Organized medicine holds that a state should make a maximum effort before receiving federal aid, but when the latter is granted, the amount should depend upon need and no other criterion.

In a recent press interview President Roosevelt indicated that he is swinging around to this point of view in connection with possible federal construction of hospitals. He pointed out that the states which can match large federal grants already have the best hospitals, while the poorer states, which urgently need additional health facilities and cannot themselves provide them, are unable to obtain sufficient financial assistance from Washington under a matched program.

Abandoning the grandiose building schemes contemplated in the Wagner and Harrison bills, the program that Mr. Roosevelt is reported to favor envisages small hospitals to be erected in sections where facilities are lacking and where local authorities give assurances that they will properly maintain and operate the institutions built for them by the federal government. The United States Public Health Service and a committee of physicians would pass on the plans for each institution and ascertain local ability and willingness to run it.

The medical profession has repeatedly expressed itself in favor of the development of adequate hospital and laboratory facilities *in communities needing them*. It has long urged *local* administration

treatment of pulmonary conditions, postoperative complications, and many advances on diverse subjects are included in this second edition with elimination of material from the first edition which is no longer useful. An extensive bibliography is included. The book should be very helpful not only to undergraduate students but also to general practitioners who desire to keep abreast of the many advances which have been made in recent years in surgery.

EMIL GORTSCH

Principles of Hematology with 100 illustrative cases and 155 illustrations including 168 original photomicrographs and 95 original charts and drawings. By Russell L. Haden, M.D. Octavo of 348 pages, illustrated. Philadelphia, Lea & Febiger, 1939. Cloth, \$4.50.

This valuable little book is an important addition to American literature on the subject. It has, within a relatively small space, all of the information on the anemias and other blood diseases that anyone except specializing hematologists is likely to require. The book is complete, authoritative, and up to date, and the style is interesting. A useful feature is the inclusion of 95 charts, which tell at a glance what it would take pages of printed matter to describe. Still another excellent feature from the point of view of teaching is that the clinical features of the hematologic diseases are covered in a section occupying one third of the volume by means of 100 illustrative case histories. Technical methods, often avoided in books of this type, are carefully described. Complex and confusing classifications, so popular at present among hematologists, are omitted and only those generally accepted and easily understood are included. There are many good microphotographs, but the inclusion of one or two colored plates would have enhanced the value of the book.

MILTON PLOTZ

Biographies of Child Development. The Mental Growth Careers of Eighty-four Infants and Children. A Ten-Year Study from the Clinic of Child Development at Yale University. Part One by Arnold Gesell, M.D., Part Two by Catherine S. Amatruda, M.D., Burton M. Castner, Ph.D., and Helen Thompson, Ph.D. Octavo of 328 pages, illustrated. New York, Paul B. Hoeber, Inc., 1939. Cloth, \$3.75.

This is another publication from the Yale Clinic of Child Development under the direction of Arnold Gesell. It presents concrete studies of individual differences in the patterning of early behavior development through the medium of clinical case records. The growth graphs in the first portion of the book are continuations of studies made ten years before with a reappraisal of the results. From this reappraisal the authors conclude that there is a "high degree of latent predictability in the early sector of the life cycle."

Part two of the book takes up individual studies of behavior growth. Cases of superior mental endowment, language problems, reading disabilities, twinship, and prematurity are studied. The authors feel that the individual differences in growth considered in these chapters are due to

differences in "(a) original capacity to grow, (b) general rate or tempo of growth, (c) patterns of developmental organization." They conclude that rather than pay too much attention to training and instruction, more would be obtained, particularly in the first five years of a child's life, through discovering and respecting his individuality.

This book is a worthy addition to the studies undertaken previously, and should be of particular interest to those interested in the growth and development of childhood.

STANLEY S. LAMM

Recent Advances in Chemotherapy. By G. M. Findlay, M.D. Second edition. Octavo of 523 pages. Philadelphia, P. Blakiston's Son & Co., 1939. Cloth, \$5.00.

The discovery of the value of sulfanilamide in the treatment of acute infections has acted as a tremendous stimulus to further investigations of chemical agents in therapy. Not since Ehrlich's discovery of arsphenamine for the treatment of syphilis has chemotherapy played such an important part in medicine as it does today.

Findlay's book on the recent advances in chemotherapy is timely and authoritative. The author reviews the recent work on various agents used in the treatment of parasites with such chemical substances as hexylresorcinol, carbon tetrachloride, tetrachloroethylene, and antimony compounds. There is an excellent chapter on alkaloids in amebiasis. Other chapters are devoted to quinine derivatives in malaria, chemotherapy of trypanosomiasis, all the arsenic compounds in syphilis, gold in tuberculosis, and the chemotherapy of leprosy. The importance of sulfanilamide and related compounds is indicated by the fact that almost one half of the book is devoted to these substances. The author closes with an excellent chapter on the chemical treatment and prophylaxis of virus infections.

No physician can be up to date without a thorough familiarity with material in the book. It is well written and highly recommended.

WILLIAM S. COLLENS

Trauma and Internal Disease. A Basis for Medical and Legal Evaluation of the Etiology, Pathology, Clinical Processes Following Injury. By Frank W. Spicer, M.D. Octavo of 593 pages, illustrated. Philadelphia, J. B. Lippincott Co., 1939. Cloth, \$7.00.

The author presents a careful study of the role of trauma as an etiologic factor in the causation of disease of the viscera and bodily structures, and discusses the etiology, pathology, clinical processes, and end-results of serious or apparently trivial injuries. He also discusses the early or late manifestations and effects of trauma upon a healthy organ or structure and also upon organs or structures that present evidence of pre-existing disease.

The book is divided into twenty-five chapters dealing with trauma and the brain, spinal cord, respiratory system, heart, lungs, etc., in a very thorough manner. In addition to being a valuable reference for the medical practitioner and surgeon, it should also be of aid to the legal profession.

According to Need

Unless federal aid for medical services is to be a form of glorified political patronage, it seems obvious that it should be distributed on the sole basis of need. One of the grave flaws in the Wagner National Health Bill was its adherence to the principle that the states must match federal grants. With this requirement in force, the richest states, which have least need of help, obtain the most money from Washington. Organized medicine holds that a state should make a maximum effort before receiving federal aid, but when the latter is granted, the amount should depend upon need and no other criterion.

In a recent press interview President Roosevelt indicated that he is swinging around to this point of view in connection with possible federal construction of hospitals. He pointed out that the states which can match large federal grants already have the best hospitals, while the poorer states, which urgently need additional health facilities and cannot themselves provide them, are unable to obtain sufficient financial assistance from Washington under a matched program.

Abandoning the grandiose building schemes contemplated in the Wagner and Harrison bills, the program that Mr. Roosevelt is reported to favor envisages small hospitals to be erected in sections where facilities are lacking and where local authorities give assurances that they will properly maintain and operate the institutions built for them by the federal government. The United States Public Health Service and a committee of physicians would pass on the plans for each institution and ascertain local ability and willingness to run it.

The medical profession has repeatedly expressed itself in favor of the development of adequate hospital and laboratory facilities *in communities needing them*. It has long urged *local* administration

and control of medical institutions, even when erected with federal funds. If the project outlined by President Roosevelt really accepts these principles, as first descriptions seem to indicate, he may count on the wholehearted cooperation of organized medicine to bring it to successful fruition.

Health for Labor

The American Labor Party is trying to win workers over to its health program by means of a bulletin issued periodically under the auspices of its Committee of Medical and Allied Professions. The Party appears determined to present the medical issues of the day fairly and to demand a square deal for the healing professions under whatever program is ultimately adopted. Unfortunately, its medical policies, as set forth in "Health Security Bulletin," appear to have been shaped by the more radical elements of which it is seeking to purge itself. Insistence on compulsory health insurance at this time, when medical and lay opinion are united on the merits of voluntary nonprofit medical expense indemnity insurance, is likely to sabotage the development of a harmonious progressive health program. Needless to say, this would cause satisfaction among Communists in and out of the A L P.

Except for the issue of compulsory insurance, there is no vital disagreement between the health programs of organized medicine and of the American Labor Party. Both favor state medical aid for the indigent and medically indigent. Both want the maintenance of the traditional doctor-patient relationship and professional participation in the administration of health plans.

The advocates of compulsory sickness insurance, in the American Labor Party as elsewhere, try to confuse the issue by arguing that voluntary insurance would not provide for all who need medical aid. This is true—but neither would compulsory insurance. The insurance principle—whether on a voluntary or compulsory basis—is applicable only to those employed at salaries large enough to permit the payment of premiums without serious deprivation. The unemployed and workers earning mere subsistence wages must receive state help. It is folly, in the name of health, to deprive small wage-earners of health essentials by levying a weekly tax on their already inadequate earnings. The unemployed do not come within the purview of compulsory insurance any more than voluntary.

The "Health Security Bulletin" of the American Labor Party argues that since voluntary insurance almost always leads to compulsory, we might just as well start with the latter. On the contrary, this seems to us another reason for not insisting on compulsory insurance until voluntary schemes have had their chance. If

voluntary insurance works out, without the creation of a vast parasitical political bureaucracy, it will be to the advantage of the working class which, in the long run, pays the costs of government. If it fails, the profession will have less reason to oppose compulsory schemes and many valuable administrative lessons will have been learned.

The American Labor Party must realize that the welfare of the working classes is indispensable to the medical profession, the vast majority of physicians have their practice among the poor and middle class. Since medicine and the American Labor Party are united on many of their health aims, would it not be a constructive step for the A L P to postpone its campaign for compulsory insurance, pending the results of voluntary medical expense indemnity, and cooperate with the profession for the enactment of measures on which they are agreed?

Total Disability

Physicians are often called upon to testify as to the degree of disability which a patient has sustained as the result of a disease or accident. Frequently, the doctor's testimony is of paramount importance in guiding the Court in its evaluation of the merits of a plaintiff's suit to validate his claim covered by a health, accident, or disability insurance contract. Some of these contracts read, in effect, that payment will be made to the policyholder if bodily injury or disease renders him *totally and permanently disabled* so as to prevent him from engaging in *any* occupation and performing *any* work for compensation.

In this connection, the decision of the St. Louis Court of Appeals in Missouri¹ brings us an important opinion, and we quote from the medicolegal abstracts of the *J A M A*: "To be permanently and totally disabled, continued the court, within the meaning of a policy of insurance such as the one sued on in this case, it is not necessary that the insured be inert and absolutely helpless, it is sufficient if it is shown that his infirmity renders him unable to perform, in the usual and customary manner, substantially all the material duties of his own occupation, business or profession or of any other occupation, business or profession which his *age, training, experience, education and physical condition would fit him for except for his disabling infirmity*." [Italics ours.]

The significance of the Court's opinion lies in the last part, namely, that it considers the disabling character of the infirmity in relation to age, training, experience, and education of the individual. Therefore physicians, when called to testify in such cases, should

¹ J.A.M.A. 114 187 (Jan. 13) 1940

and control of medical institutions, even when erected with federal funds. If the project outlined by President Roosevelt really accepts these principles, as first descriptions seem to indicate, he may count on the wholehearted cooperation of organized medicine to bring it to successful fruition.

Health for Labor

The American Labor Party is trying to win workers over to its health program by means of a bulletin issued periodically under the auspices of its Committee of Medical and Allied Professions. The Party appears determined to present the medical issues of the day fairly and to demand a square deal for the healing professions under whatever program is ultimately adopted. Unfortunately, its medical policies, as set forth in "Health Security Bulletin," appear to have been shaped by the more radical elements of which it is seeking to purge itself. Insistence on compulsory health insurance at this time, when medical and lay opinion are united on the merits of voluntary nonprofit medical expense indemnity insurance, is likely to sabotage the development of a harmonious progressive health program. Needless to say, this would cause satisfaction among Communists in and out of the A L P.

Except for the issue of compulsory insurance, there is no vital disagreement between the health programs of organized medicine and of the American Labor Party. Both favor state medical aid for the indigent and medically indigent. Both want the maintenance of the traditional doctor-patient relationship and professional participation in the administration of health plans.

The advocates of compulsory sickness insurance, in the American Labor Party as elsewhere, try to confuse the issue by arguing that voluntary insurance would not provide for all who need medical aid. This is true—but neither would compulsory insurance. The insurance principle—whether on a voluntary or compulsory basis—is applicable only to those employed at salaries large enough to permit the payment of premiums without serious deprivation. The unemployed and workers earning mere subsistence wages must receive state help. It is folly, in the name of health, to deprive small wage-earners of health essentials by levying a weekly tax on their already inadequate earnings. The unemployed do not come within the purview of compulsory insurance any more than voluntary.

The "Health Security Bulletin" of the American Labor Party argues that since voluntary insurance almost always leads to compulsory, we might just as well start with the latter. On the contrary, this seems to us another reason for not insisting on compulsory insurance until voluntary schemes have had their chance. If

URGENT

C—4 and Progress Reports of Workmen's Compensation Cases

The following letter from Industrial Commissioner Frieda S. Miller shows the great importance to all concerned of the *prompt* filing of reports and the necessity of sending in to insurance carriers and the Department of Labor detailed progress reports every three or four weeks.

'The free choice medical provisions of the Workmen's Compensation Law have placed great responsibility on the medical profession for the proper functioning of certain aspects of workmen's compensation.

"The prompt and frequent filing of adequate medical reports by attending physicians does much to expedite the payment of compensation to injured workmen as their wages would have been paid. Delays in the filing of reports, and the filing of inadequate reports, on the other hand, tend to thwart the intent of the law that compensation shall be paid promptly and periodically.

"Insurance companies in explaining delay in making the first payment and in refusing to continue payments pending later hearings insist that the absence of medical reports or inconclusive medical reports from attending physicians is responsible. They will point out that the medical reports have not been received, or that there is no indication of need for further treatment. Medical reports frequently fail to indicate that the disability continues, or state, in stereotyped form from report to report, that the same physical findings are continued without indicating what progress has been made.

"The effect of the delays in making payments is to circumvent the explicit intention of the Workmen's Compensation Law, that benefits be paid as wages are paid. Formerly employers and insurance companies could be held to have knowledge of the claimant's need for treatment since they themselves were responsible for providing medical attention.

"The law now provides that unless the claimant's claim is controverted, payment shall become due on the fourteenth day of disability and shall be paid within four days thereafter. Legislation is being proposed which will assess the carriers for failure to pay within the prescribed period. In addition to this assessment there will be another provided for every case in which notice of controversy is filed and an award subsequently made. It is hoped that these proposals will bring about the prompt payment of compensation to injured workmen.

"It would hardly be fair, however, to assess insurance carriers, unless adequate medical reports on which to base their decisions can be made available in time. The complete cooperation of attending physicians is therefore urgent if early and continuous payment of compensation is to be achieved."

In other words, file reports promptly and keep the carrier and the Department of Labor informed of the medical progress of the case.

All physicians are urged to cooperate.

DAVID J. KALISEI, M.D., Director

Bureau of Workmen's Compensation, Medical Society of the State of New York

give mature consideration to this phase of the problem so that they can materially contribute to the solution of what constitutes *total disability* in a given case

Cerebral Damage from Hypoglycemia

In the treatment of diabetics with insulin, and particularly with protamine zinc insulin, there is ever present the possibility of inducing a state of hypoglycemia. The potential danger of this lies in the fact that one cannot predict the occurrence of such a reaction, since the response to insulin therapy varies not only in different individuals but often in the same patient at different times. Furthermore, the usual prodromal signs and symptoms of an impending hypoglycemia are frequently so altered when protamine zinc insulin is used that the recognition of this state is not readily apparent to the patient.

Layne and Baker¹ have observed 7 cases of diabetes wherein a hypoglycemia produced definite cerebral damage. As the result of this, 4 died and postmortem findings confirmed the clinical observations. In the younger age group particularly, where death is less apt to occur, permanent disabilities in the neurologic and mental status follow the hypoglycemia. Diabetics who have an associated chronic disease which in itself may affect cerebral tissues are extremely susceptible to the slightest degree of a reduction in the blood sugar below the normal. Here, too, the cerebral damage is often irreversible. Layne and Baker further stress that one must be cautious in administering insulin to a comatose diabetic since a hypoglycemic coma may easily be mistaken for a diabetic acidosis.

If the patient survives the injury to his brain tissues, the return of the blood sugar to a normal or slightly elevated level has but little effect on the course of the neurologic picture. Therefore not only the patient, but his family as well, should receive detailed instruction in the recognition of the earliest signs of hypoglycemia so that the physician can be immediately called to forestall the development of a severe reaction.

¹ Layne J A, and Baker A B. Minn. Med 22 771 (1939)

Sale of Hypnotic or Somnifacient Drugs

On January 21 the Department of Education and the Department of Health of New York State announced, among other new rules which had been adopted by the Board of Regents, a very important rule, No 30, as follows:

No hypnotic or somnifacient drug intended for internal use shall be sold at retail or dispensed to any person except upon the written prescription of a physician, a dentist or a veterinarian, and the prescription shall remain on file in the pharmacy where compounded. Such prescription shall not be refilled if it bears indication by the physician, the dentist or the veterinarian that it is not to be refilled.

Formerly employers and insurance companies could be held to have knowledge of the claimant's need for treatment since they themselves were responsible for providing medical attention.

"The law now provides that unless the claimant's claim is controverted, payment shall become due on the fourteenth day of disability and shall be paid within four days thereafter. Legislation is being proposed which will assess the carriers for failure to pay within the prescribed period. In addition to this assessment there will be another provided for every case in which notice of controversy is filed and an award subsequently made. It is hoped that these proposals will bring about the prompt payment of compensation to injured workmen.

"It would hardly be fair, however, to assess insurance carriers, unless adequate medical reports on which to base their decisions can be made available in time. The complete cooperation of attending physicians is therefore urgent if early and continuous payment of compensation is to be achieved."

In other words, file reports promptly and keep the carrier and the Department of Labor informed of the medical progress of the case.

All physicians are urged to cooperate.

PRIMARY ILEOCECAL TUBERCULOSIS

BURRILL B. CROHN, M D, and HARRY YARNIS, M D, New York City

(From the Medical Services, Mount Sinai Hospital)

LESS than ten years after Robert Koch had stained and had cultured the tubercle bacillus, there appeared in the literature of France and of Germany, clinical accounts of cases of so-called primary intestinal tuberculosis. Most of the case histories which followed were derived from surgical operations and were considered as instances in which the ileocecal region was the primary seat of tuberculous infiltration. The disease process was restricted to this area, producing a localized effect susceptible of successful resection. Dissemination of the infection was not observed in these earlier primary cases, the lungs, bones, joints, and other viscera being exempt in the earlier or operable stage.

The history of the spread of the concept of primary intestinal tuberculosis is interesting as denoting the acceptance of the idea by the profession, and its almost immediate popularization.

General interest in the subject is credited to Hartman and Pilliet,¹ who in 1891 operated upon two such cases, they regarded the disease as an attenuated form of localized tuberculosis analogous to lupus. Their clinicopathologic descriptions are loose and unsupported by bacteriologic proof.

In 1898, Conrath² was quoting authors such as Klebs and Leube, who had already then doubted that primary ileocecal tuberculosis ever occurred, yet he himself proceeded to abstract from the literature 85 such cases, many of which seemed plausible, but many others of which were unquestionably mixed forms of pulmonary phthisis and secondary intestinal tuberculosis. He emphasized the longevity and excellent prognosis following successful localized resections, he leaves the subject, however, confused.

In 1900, Hugel³ described 3 similar primary cases, in all of which tubercle bacilli were found in the sections and in all of which the hyperplastic ileocecal resected mass fell into the conventionally accepted pathologic category. These seem to be bona fide cases.

Lartigau⁴ published a case of diffuse ileal and colonic tuberculosis apparently primary to Addison's disease, bacteriologically confirmed.

But soon the confusion begins or becomes intensified, for with the greater popularization of the subject, the literature is observed to contain many case reports in which the various factors lack clear-cut consideration. Before the advent of radiography, involvement or non-involvement of the lungs as a primary effect rested on physical signs, on auscultation and percussion, methods which we realize today were hardly efficient in delineating early phthisis as a possible primary focus whence might be derived the secondary intestinal deposit.

In nearly all the operated cases the local descriptions are excellent, but the general physical status of the patient is treated with insufficient mention, and the bacteriologic and animal confirmation of the hypothesis of a primary intestinal infection remains mostly unproved.

Yet the subject becomes a popular one and the literature grows apace until shortly, or even up to comparatively recent times, the impression is gained, by listening to discussions by clinicians, or by reading current literature, that ileocecal tuberculosis is indeed a common disease to be expected and encountered in all lower right abdominal explorations. Every mass found in the lower right quadrant was, if not neoplastic, then probably tuberculous, regardless of whether tu-

Read at the Annual Meeting of the Medical Society of the State of New York, Syracuse, April 27, 1939

bercle bacilli were found in the slides or whether animal inoculation verified the original supposition

With the more latterly recognition of the greater frequency of nonspecific granulomatous processes of the entire alimentary tract,^{5,6,7} and particularly of the terminal ileum,^{8,9} it became apparent that the neglect to recognize these nonspecific varieties was due to the fact that they had previously all been considered as tuberculous processes whose specificity, though unproved, was still the most likely hypothesis

With the acceptance of granulomata, terminal ileitis, and regional enteritis, as well as of right-sided colitis and their mixed forms, it became apparent that the percentage of cases of true primary intestinal tuberculosis seemed to follow the law of diminishing returns, the whole question of the incidence and frequency, if not the actual clinical entity of primary intestinal tuberculosis, called for reconsideration. To a large extent the nonspecific granulomata have replaced almost entirely the tuberculous concepts. In our own experience in the last eight years, we have recognized ileitis, right-sided or regional colitis in 130 instances, during which time we saw so few proved cases of primary intestinal tuberculosis that we were led to doubt the very existence of such a specific form of intestinal infection

With these doubts and skepticisms in mind we have considered it well worthy to reopen the question of the relative incidences of specific and nonspecific forms of ileocecal inflammations, to note their relative frequencies, and to reappraise more critically the concept of primary ileocecal tuberculosis

The "Case" for Primary Intestinal Tuberculosis—In the concept of Calmette¹⁰ and of his associate, Guern,¹¹ the intestinal mucosa is the portal of entry in the largest percentage of cases of tuberculosis. Calmette¹⁰ considered the intestinal mucosa as pervious to viable tubercle bacilli, the organism penetrating the unbroken or the traumatized mucous membrane of the crypts of Lieberkuehn

to reside in the mesenteric lymph nodes as caseous or calcified primary effects. Thence, in course of time, the spread took place by way of the abdominal lymphatics to the thoracic duct, to the bronchial lymph nodes, and eventually to the lungs or to the general circulation. In his view, the intestinal mucosa was the "chancere of inoculation," and bovine tubercle bacilli derived from contaminated cow's milk the favorite source of the infecting material

The original portal of intestinal entry was rarely the site of the lesion, due to the fact that the organisms traversed the mucous membrane without residing therein, and penetrating freely, became engulfed in the nearest regional lymph nodes, the mesenteric, there to create the first station of tubercle formation. Certain realities made this hypothesis a plausible one. A large percentage of milch cows in the beginning of the century were infected with tuberculosis, a goodly percentage of the drinkable milk might therefore have contained viable bacilli, pasteurization was not then practiced

By actual feeding experiments to young calves and other laboratory animals, Villemin¹² was able to produce or to reproduce intestinal tuberculosis, the virus or inoculum was fed in the form of the infected viscera of other tuberculous cows or of macerated viscera from autopsy material of human tuberculosis. Intestinal tuberculosis in animals, followed shortly by generally disseminated tuberculosis, could thus be reproduced

Outside of France the views of Calmette did not meet with general approbation, the fact remaining that primary intestinal tuberculosis was rare, and that the percentage of bovine infections in human beings was relatively infrequent, though not inconsiderable.

The Royal Commission in England in 1931¹³ typed a total of 1,597 cases of tuberculosis in man and found an incidence of 22.2 per cent of bovine infections. The occurrence of bovine infection in man varied with age periods, particularly common in the first four years of life and declining with advancing years

Blacklock,¹⁴ in England, found that 80.4 per cent of all abdominal tuberculosis in children was bovine, the Royal Commission had reported that of the 19 cases caused by the bovine organisms, 73.7 per cent were intestinal tuberculosis. They found that in 372 autopsies of tuberculous children, 123, or one-fifth, were of bovine origin.

Mitchell,¹⁵ in Edinburgh, examined 72 fatal cases of cervical tuberculosis in children under the age of twelve years and found that 90.3 per cent of the cases yielded the bovine organism.

In New York City, Park and Krumwiede¹⁶ isolated the human organisms in all but one of 305 adults, while in 117 children under the age of five years, 25 (21.4 per cent) yielded the bovine strain of the organism.

Thus our attention becomes focused on three facts: (1) the bovine strain is capable of infecting human beings, (2) it is most commonly found in children during the years when milk drinking forms the essential part of their diet, (3) that abdominal tuberculosis represents by far the greatest percentage of infected cases. This, coupled with the fact that as recently as 1917, 10 per cent to 35 per cent of our rural milk herd were positive tuberculin-reactors, would lead us to expect a high incidence of primary intestinal tuberculosis in internal medicine and particularly in pediatrics.

The "Case" Against Primary Intestinal Tuberculosis—Does the clinical experience bear out the hypothesis of Calmette, and what is actually our experience with the incidence and symptomatology of primary intestinal tuberculosis in man?

There are few figures in modern clinical medicine which attempt to state the incidence of primary intestinal tuberculosis, nor would such figures be likely to be very reliable. Gay¹⁸ questions that primary human adult intestinal tuberculosis actually exists, Herrick¹⁹ states that in the Lakeside Hospital, there were no primary intestinal cases in 800 autopsies, and that at the Cleveland Hospital, only 1 case in 2,900 autopsies. Beitzke,²⁰ in 1908, in 100 autopsies, found only 13 cases

of primary intestinal tuberculosis, accepting only proved cases. Ferris,²¹ at New York Hospital, in 1937, found in 1,190 autopsies only 33 cases of calcified tuberculous lymph nodes in the mesentery, in 3 of these cases he found also calcified areas in the intestinal mucosa. Yet the histologic verification of the tuberculous nature of these latter cases is unconvincing and in only 1 case was one tubercle bacillus seen in one slide only.

Tedious as it is to review and criticize the more recent literature, it is necessary to do so in order to arrive at some conclusion concerning the trustworthiness of their reports and to deduce a correct conclusion regarding the pathologic incidence of the disease.

Richter,²² in 1906, regarded ileocecal tuberculosis as only an accidental infection with cicatricial swelling, he and others have considered the supposition that the original process in the intestine was actually a nonspecific granulomatous one in which a few stray tubercle bacilli were incidentally enmeshed. Successfully he operated upon 3 such cases, all the patients being subsequently reported as well. But his first 2 cases were possibly, if not probably, typical terminal ileitis in which no tubercle bacilli were ever found, in his third case, acid-fast organisms were detected in only one slide. His cases were all young people under 30 years of age, he made no mention of having sought for possible tuberculous foci elsewhere in the body. When one considers that regional ileitis is also a disease of youth, the possibility of confusion must be strongly entertained.

Brunner²³ cited 2 personal cases of which 1 had obvious pulmonary tuberculosis, no bacteriologic studies were made in either case. He does feel however, with others, that the intestinal lesion remains stationary because of the low virulence of the infecting organism and the attenuation of its strength (bovine?) in the human intestinal tract.

Counsellor,²⁴ in 1929, reported a case of primary tuberculosis of the ileum in a woman 40 years of age. The lesion was high in the ileum, 90 cm from the ileo-

cecal valve, thick, plastic, and granulomatous. A nodule was said to be proved tuberculous, but the details of the verification were missing. It should be recalled that regional ileitis occurs also in isolated patches high in the ileum and jejunum and resembles in most particulars a tuberculous lesion, though actually nonspecific in origin.

Counsellor's case may have been a true case of primary tuberculosis, though his facts are not convincing since there is no exact description of histology nor any reference to a possible tuberculous area elsewhere in the body.

Dixon and Bearer²⁵ report a case of nonspecific granuloma of the ileum and cecum with perforating sinuses; they found tubercle bacilli in one lymph node. They state that most of the lesion was healing or healed, and now nonspecific in character. It is hard to deny the tubercle bacilli in the lymph node and yet all the other characteristics of their case smack of typical nonspecific ileitis and colitis.

Crossman,²⁶ in 1936, published what seems to have been an indisputable case of diffuse primary tuberculosis of the whole ileum. Tubercle bacilli were found in all of the stained specimens and the lungs are distinctly said to have been free of the disease. He speaks of the process as one of local allergy to a bovine strain of the bacillus, with an exaggerated local reaction. He considers that the tuberculous organism played a relatively small part in the process.

To summarize the literature, the opinion of bacteriologists varies from those of Calmette who regarded the intestinal point of origin for human tuberculosis as the most common one, to those who deny entirely the existence of primary intestinal tuberculosis. The surgical fraternity has published many cases of supposed initial intestinal tuberculosis, but in most of the published material true bacteriologic verification is missing and the differentiation from nonspecific granulomata, particularly before the recognition of regional ileitis and allied nonspecific processes, is completely omitted.

Only the pediatricians seem to offer a very minimal incidence of true primary intestinal effects, most of these in children below four years of age, in the milk-drinking period, and most of these of bovine origin and nature.

Because of the great tendency to confuse specific processes (tuberculous) at the ileocecal junction with nonspecific processes, most of the literature before 1932 is unreliable. Both the gross and histologic appearances of specific and nonspecific processes are very similar, unless careful bacteriologic studies and animal inoculations are performed, the two cannot be differentiated with any likelihood of accuracy. The lack of mention and the lack of search for primary foci of infection elsewhere in the body were notoriously absent in many of the published cases.

Personal Experiences with Primary Intestinal Tuberculosis. A careful survey and review of all autopsy material and all surgically resected specimens has been made at Mount Sinai Hospital covering the period of the last twelve years (1926 to 1938). After carefully reviewing the pathologic material of the past twelve years (4,800 autopsies and all the surgical material), after eliminating all the granulomata of nonspecific origin and nature, we are left with 8 cases of what we must accept as primary intestinal tuberculosis of conceded histologic and gross structure.

In the 4,800 autopsies we were able to substantiate only one case of primary intestinal tuberculosis, an extremely low incidence, and one that bears out the statements from the Cleveland Hospitals. The other 7 instances were culled from the general surgical pathologic material and represent resections in active cases. Apparently, then, in searching for clinical material of this type, the surgical resections are more likely to be rewarding than is the autopsy material.

The fact that the Mt. Sinai Hospital is a general hospital, in which known tuberculous cases represent only a small percentage of clinical material, does not vitiate these statistics. Institutions

TABLE 1—PRIMARY INTESTINAL TUBERCULOSIS—CLINICAL DATA

generalized miliary tuberculosis				

known as specialized hospitals for tuberculosis are of two kinds, those handling phthisis and those devoted to the treatment of tuberculosis of bone, joint, and glands. In neither of these institutions would primary intestinal tuberculosis be likely to be discovered. On the other hand, a general institution with a large surgical and abdominal clientele would offer a much better chance of early perception and early resection of a primary intestinal focus.

An analysis of these 8 cases of presumably proved intestinal tuberculosis is most enlightening. The age limits fall between twelve years for the youngest and fifty-five years for the oldest person, or as follows:

AGE INCIDENCE OF 8 CASES OF PRIMARY INTESTINAL TUBERCULOSIS

12 years	Female
18 years	Male
18 years	Male
18 years	Male
22 years	Female
28 years	Male
29 years	Female
55 years	Female

It will be seen that almost all of the cases occurred in young persons in the second and third decades of life, the only exception was the female, fifty-five years of age. This fact would coincide with the well-accepted dictum in the literature that intestinal tuberculosis, when pri-

mary, is a disease of youth. We saw no cases in the first years of life. If the infection is really due to bovine strain and is an effect of contaminated milk drinking, then we are seeing the cases not at the period of earliest invasion (infancy) but in the later adolescent years when the primary mesenteric form no longer remains localized but has now proceeded to the secondary stage of invasion of neighboring intestinal viscera. In the thoracic type of tuberculosis, the infection in the bronchial lymph nodes extends by lymphatic invasion to the apices of the lungs and its parenchyma. In the abdominal type, the mesenteric lymph node breaks down and invades, by retrograde lymphatic extension, its neighboring viscera, namely, the intestinal mucosa and serosa. This second stage presumably follows the first infestation only after a lapse of many years.

The sex distribution was exactly even, namely, 4 males and 4 females. Of the 8 cases only 4 were white natives of the northern states of this country. Two patients were Puerto Ricans, 1 a Negro, and 1 a Hindu. In the instances of these latter 4 cases, it may be presumed that in their childhood they were possibly or probably exposed to unpasteurized raw milk of tuberculous contamination. While this cannot be proved as a fact, it is a presumption.

Pathology The pathologic material was obtained in 7 instances from surgically resected specimens, in 1 instance only from a complete autopsy (Table 2)

The gross lesion as described varies from simple, shallow, discreet, multiple ulcerations to ulcerations with granulomatous reactions and with localized mass formation. In some instances true hyperplastic ileocecal tuberculosis with or without stenosis is represented. In one instance a stenosing hyperplastic lesion of the ascending colon was observed, in 2 cases tuberculous fistula-in-ano were complicating factors.

The gross and microscopic appearances were typical of the lesion of ileocecal hyperplastic or ulcerous tuberculosis as so ably described in textbooks such as Brown and Sampson,²⁷ and Berard and Patel.²⁸ It is questionable whether anyone could differentiate by inspection the primary type of lesion from the secondary type of extension which occurs as a late complication or as a terminal event in the pulmonary form of tuberculosis. Grossly, the lesion could not always be differentiated from nonspecific granulomata. The discreet ulcerous type and those involving only the cecum were quite characteristic of primary tuberculosis. The hyperplastic granulomata of the cecum and ascending colon with minimal involvement of the ileum resembled very closely regional or segmental right-sided colitis, only a microscopic and careful bacteriologic examination being capable of a clear differentiation. True terminal ileitis without colonic participation could rarely today be mistaken for hyperplastic ileocecal tuberculosis.

In all cases, the mesenteric lymph nodes were enlarged and firm and definitely pathologic. In one case only was true caseation seen, in the remaining cases the mesenteric nodes of tuberculosis resembled those seen in ileitis, characteristic miliary tubercles being often absent, at least on gross inspection.

In one fatal case the autopsy disclosed the extension of a caseous mesenteric lymph node to the thoracic duct. Two cm above the diaphragm the thoracic

duct was ulcerated and contained necrotic tubercles, slightly above this area the thoracic duct was occluded by caseous necrotic material. In this instance death was due to a generalized miliary tuberculosis involving the abdominal and thoracic viscera. This case is extremely important as it marked a true and clear-cut instance of the transition of a primary intestinal focus to a disseminated miliary form of general disease.

Symptomatology The duration of active symptoms varied from two weeks to eight years, averaging one and one-half years for all the cases. Diarrhea (moderate in nature), low-grade temperature, and abdominal pain (colicky in nature and associated with defecations) were the principal outstanding clinical features. Loss of weight was considerable, and a secondary anemia usually a constant phenomenon.

Sooner or later almost all cases exhibited a mass in the lower right quadrant. The mass is described as small and globular, or as sausage-shaped, movable, and tender. The appearance of anal fistulas containing caseous granulomatous material was in 2 instances an important confirmatory sign of the nature of the lesion (Figs 1 and 2).

It will be noted however, that these symptoms, even including the perianal fistulas, are in no way dissimilar to those seen in ileitis and segmental or right-sided colitis. Hence the confusion in the past, and for that matter, in the present, in differentiating the specific tuberculous from the nonspecific forms of ileal and cecal disease.

Radiographically the two types, specific and nonspecific, fail of complete differentiation. The typical "string-sign" of true terminal ileitis is rarely seen in tuberculosis. But the phenomenon of irritable nonfilling of the cecum and ascending colon, as demonstrated by Sampson and by Sterlin, while more typical of tuberculosis, is also seen in right-sided or segmental colitis. Strictured areas are typical of tuberculosis and do not occur in regional colitis.

Prognosis As was to be expected, the

Primary Intestinal Tuberculosis

FIG 1

Primary Intestinal Tuberculosis

FIG 2

prognosis of ileocecal tuberculosis, even after resection, was not good. One case was not improved, 3 cases recurred extensively, 2 cases died. In 2 instances favorable results were achieved, 1 patient having remained apparently well when last seen.

Bacteriologic verification. One of the most important questions arising in the consideration of these 8 cases concerns itself with the bacteriologic confirmation of the diagnosis. In all the instances the diagnosis was made upon typical histologic evidence of miliary tubercle formation with mononuclear cells and giant cells characteristic of classical tuberculosis. The data in the 8 cases were as follows:

BACTERIOLOGIC DATA IN 8 CASES OF PRIMARY
INTESTINAL TUBERCULOSIS

Case	
T R.	Caseous lymph nodes no acid-fast organisms negative guinea pig inoculation
E B	Typical tubercle formation acid fast organisms in mesenteric lymph nodes positive negative guinea pig and rabbit inoculation
A G	Caseous tuberculous lymph nodes diffuse miliary tuberculosis (autopsy)
W K	Typical miliary tubercle formation
A A	Typical miliary tubercle formation no bacilli in slides
H S	Typical miliary tubercle formation no bacilli in slides
E. P	Typical miliary tubercle formation, tubercle bacilli in pus from anal fistula
C B	Typical miliary tubercle formation

It will be seen that our greatest reliance was placed upon the histologic diagnosis of true tubercle formation with giant cells and characteristic caseation, the slides being taken from the intestinal lesion and the adjoining mesenteric lymph nodes. In 2 instances only, were typical acid-fast organisms seen in the slides, in one of these cases inoculation of rabbits and guinea pigs with fresh pathologic material failed to reproduce the disease in these laboratory animals. We are to be criticized for not having performed more often animal inoculation with suspected tissue material. It is remarkable, however, that in the 2 instances when attempts were made to transmit the inoculum to animals, both failed to reproduce the disease. Perhaps the acid-fast organisms were too attenuated to cause infection in the animals, surely an evidence of the attenuation of the strength of the offending

bacilli in both of these cases. We believe that the ultimate scientific proof of the existence of the tuberculous nature of these cases would require not only a histologic verification, but the finding of the acid-fast organisms in all of the slides as well as of successful inoculation of guinea pigs or of rabbits with the suspected pathologic material. This ultimate proof we cannot furnish in these cases, and yet we are not ready to dismiss these specimens as nontuberculous, but believe and hope that most pathologists and most bacteriologists will agree in accepting the specific nature of the primary intestinal effects as we have described them. Many bacteriologists will refuse to accept as tuberculous any material that fails to produce the disease in guinea pigs, since the latter animals are highly susceptible to even a very small number of viable organisms. Many pathologists will decline to accept as tuberculosis, slides and specimens in which organisms of the acid-fast variety cannot be demonstrated. Yet the clinical nature of the disease, the course and spread, the associated lesions and other organs, and the typical histologic appearance of the miliary tubercles have led us, consciously and critically, to accept these 8 cases as tuberculous in nature and as caused by the mycobacterium of tuberculosis.

For that matter, if the accepted literature on primary intestinal tuberculosis were to be strictly and critically analyzed, and if one were to exclude and eliminate all those published cases lacking the demonstration of acid-fast organisms and lacking successful animal inoculations, there would not be material left to represent a single convincingly proved case. In the published surgical case reports there is practically no mention of animal inoculation and I can recall no instance where both bacilli were shown in slides and positive guinea pig transmission was successfully carried out.

Nonspecific Granulomata. During the twelve years represented in the above study we collected 8 cases of presumable primary ileocecal tuberculosis. During

the last six years (or half that time) we have encountered 130 cases of nonspecific regional ileitis and segmental colitis. The discrepancies between the incidences of these two forms of disease are most striking. Had we known nonspecific ileitis before 1932 we would undoubtedly have added a considerable additional number of cases to the 130 specimens actually studied.

Evidently, the nonspecific granulomata, ileitis, and regional colitis far outnumber primary intestinal tuberculosis as a clinical finding in the ratio of 32.5 to 1. The relative scarcity of intestinal tuberculosis, as of today, in comparison with the nonspecific forms, may be explained on several grounds. The primary reason consists in the fact that all these nonspecific forms, like ileitis, were previously regarded as tuberculosis, though the scientific proof was carelessly lacking or was rarely sought for. By eliminating the nonspecific forms from all the right lower quadrant granulomata, we find, on analysis, that very little remains as true tuberculosis.

In the second instance, primary intestinal tuberculosis, if ever a frequent disease, seems now definitely on the wane. This is to be accounted for by the fact, as pointed out by all bacteriologists, that bovine herd infestation by tuberculosis has been almost completely eliminated. Since May, 1918, from 3.0 to 49.6 per cent of milch cows in the State of New York have been slaughtered because of tuberculosis, in January, 1938, less than 0.46 per cent of the registered herd in this state were estimated to be carriers of bovine tuberculosis.¹⁷ This means the practical elimination of infected milk, which, added to the widespread acceptance of pasteurization, means the wiping out of contaminated bacillus-carrying milk.

If primary intestinal tuberculosis is an infection of the human child, transmitted by milk contaminated with the bovine bacillus or tuberculosis, then the cause for the relatively greater paucity of such cases is seen in the highly successful and highly laudable work of our Health Departments

and State Dairy Commissions in eliminating bovine tuberculosis and insisting upon pasteurization of the bulk of milk carried to our markets.

The fact is that the nonspecific granulomata constitute the great bulk of cases of ileocecal hyperplastic disease. Ileitis alone far outnumbers primary intestinal tuberculosis, Hodgkin's disease, and multiple sarcomatosis, all combined.

In the differential diagnosis of lower right quadrant abdominal masses it is necessary, in teaching, to realize the greater frequency of ileitis and regional colitis, and to relegate to diseases of great rarity, primary intestinal tuberculosis, and other specific types of inflammation.

It may even be that shortly, with the continued success of public health measures and the vigilance of our praiseworthy servants, the entire concept and incidence of primary human intestinal tuberculosis will disappear as a clinical finding and a pathologic entity.

TREATMENT OF OPERABLE RECTAL CANCER

GEORGE E. BINKLEY, M B (Tor), New York City

RECTAL cancer is a comparatively common disease. It is encountered most frequently in those of mature age, but it may occur any time after puberty. The incidence of this disease in America, according to statistics, is on the increase. This increase may be more apparent than real, due to the greater average age of the population. Cancer in this location lends itself to easy recognition. Its treatment constitutes one of the most important present-day surgical problems.

Early recognition of rectal cancer is very important from the standpoint of successful treatment. It is impossible to overemphasize the importance of this factor. The earlier the disease is recognized, the greater the possibilities of complete eradication. Early diagnosis is largely in the hands of the general practitioner, gastroenterologist, and internist. Seldom do patients first consult a surgeon for rectal symptoms. In the very early stages, symptoms may be mild and indefinite but they usually suggest to the patient that he has a rectum, and that something is abnormal in that section of bowel. Any alteration from the normal functioning of the bowels, characterized by constipation, increasing constipation, gaseous distention, mild attacks of cramp-like pain, especially in the left lower abdominal quadrant, a few drops of blood on stool or toilet paper, increased amount of mucus with stools, mild tenesmus, etc., are symptoms strongly suggestive of early new growth and are worthy of careful investigation. The above symptoms suggest the possibilities of cancer but a definite diagnosis can be made in the early stages only by very careful rectal examinations.

Rectal examinations consist of palpation of the rectum with the finger, and instrumentation with an electrically

lighted sigmoidoscope. The latter is a simple office procedure and may be completed within a few minutes without distress to the patient. Incomplete or careless examinations are to be condemned as they seldom reveal a satisfactory explanation of the symptoms, and frequently convey a false impression as to the presence of cancer. A higher percentage of early diagnoses would result from education of the laity to seek medical advice for all minor anal and rectal symptoms, and from an increased willingness of the profession to investigate all symptoms that suggest pathology in the terminal intestinal tract by a thorough rectal and sigmoidal examination.

In most instances a definite diagnosis of rectal cancer can be made by the experienced clinician, from clinical findings. However, there are atypical, nonmalignant tumors which closely resemble cancer, concerning which even the experienced may be in doubt. Removal of a rectum is an operation not to be undertaken lightly or without necessity. In order to avoid an occasional mistake, the clinical diagnosis should be confirmed by submitting a piece of tissue to a well-trained tumor pathologist for histological study before treatment is undertaken. If the first biopsy fails to show malignant change and the clinical appearance suggests malignancy, further sections should be submitted. From past experience it is quite evident that biopsies are frequently necessary. A number of patients with nonmalignant polyps and others with nonmalignant rectal pathology have been advised to have rectal resection, under the erroneous impression that they were suffering from cancer. The old idea of hastening the dissemination of cancer cells by taking a small piece of tumor tissue for examination appears

*Read at the Annual Meeting of the Medical Society of the State of New York,
Syracuse, April 27, 1939*

to have little foundation. There is no real proof of such reaction. Only by routine biopsies, especially with atypical tumors, is the surgeon sure of avoiding the embarrassing mistake of removing a nonmalignant rectum or permitting a cancer which appears nonmalignant to reach an advanced stage before its true nature is determined.

The second step in the care of rectal cancer is the classification of patients as to treatment and prognosis. Patients may be separated into two main groups, namely, operable and inoperable. This classification is often possible after appraisal of routine laboratory, general physical, and rectal examinations. In a certain percentage of cases further studies are advisable, such as detailed investigations of the cardiovascular system, roentgenographic examinations of the chest, pelvis, and lumbar spine for metastases, and cystoscopic examinations of males where the tumors are on the anterior rectal wall adjacent to the bladder. From the above investigations one can determine the operability, or at least the advisability of an exploratory operation. At times it is difficult to determine the exact extent of metastatic and local disease without an exploratory laparotomy. The inoperable group comprises those patients who, because of extensive disease or very poor physical condition, are unsuitable for radical treatment. The operable group includes those patients for whom radical forms of treatment offer the greatest possibilities as to cure and palliation. The operable group, in accordance with the extent of the disease, may be subdivided into (a) early operable, (b) medium-advanced operable, and (c) borderline or advanced operable groups. They may be classified further as to the general condition of the patient or his ability to withstand treatment, into good, medium, and poor surgical risks.

One of the problems in treatment of rectal cancer is in selecting the treatment most suitable for the given case. The selection is enhanced by a working knowledge of the advantages and limitations of the recognized surgical procedures for re-

moving a cancerous rectum, and of the value of radiation therapy in this disease. Radical surgical removal of the tumor and adjacent tissues is the method of choice in most instances. Radiation therapy, also considered a surgical method, is of value in a certain percentage of cases. It may be employed, alone, to eradicate the disease, or used to supplement radical resection. In certain instances the surgeon has a choice of procedures, any one of which is likely to produce the desired result, while in other cases one particular form of treatment or type of operation suggests advantages additional to that of any other well recognized method.

The types of surgical operations which appear of greatest value and are employed most extensively, are first, those which include an abdominal as well as a perineal approach, and second, those which have only a perineal approach for removing the tumor. These may be completed after a preliminary abdominal colostomy has been constructed, or the resection may be done without exploration or an abdominal colostomy. In the latter, the sigmoid is brought down and used to form a perineal anus at the site of the incision. The above methods are almost standard procedures. Many surgeons, however, vary the technic slightly from that originally described by the authors. Selective surgical methods, whereby the chief objective is continuity of bowel and sphincter control, so as to avoid an artificial opening, are preferred by a few surgeons. Operations of this nature have a selective field in the early stages of the disease, but cannot be considered for routine employment in the more advanced operable stages. The limited dissection afforded by many of these operations too frequently results in incomplete removal and early recurrences.

Abdominoperineal resections appear to be the most ideal for eradicating rectal and rectosigmoidal cancer, as they provide for the widest dissection of lymphatic channels and adjacent tissues. Cancer in these locations spreads by continuity of tissue and by the lymphatic and blood

streams Dissemination by the blood stream is beyond the reach of surgical operation Extension by continuity of tissue or dissemination by the lymphatic route may still be within reach of the more radical dissections The preliminary abdominal approach affords the greatest possibilities for removing upward and lateral lymphatic channels, as well as a wide dissection of tissues surrounding the upper rectum and rectosigmoidal junction By the secondary or perineal approach the lower part of the dissection is continued and the condemned tissues removed A new pelvic floor is constructed and the patient retains a permanent abdominal colostomy Such thorough resections may be completed at one time, as advocated by Miles, or may be concluded in two stages, as suggested by Lahey, Coffey, and others

The one-stage abdominoperineal or Miles' type of operation is the surgical method of choice It is applicable for tumors located anywhere within the rectum and at the rectosigmoidal junction Patients are spared the anxiety and worry of two operations The perineal wound heals rapidly and hospitalization is comparatively short The percentage of cases for which this operation is suitable will depend upon the general condition of the patient and extent of disease It is most suitable for those in good or fairly good physical condition, who are fortunate enough to have their cancer recognized while in the early or medium-advanced operable stage of development.

Abdominoperineal resections in two stages, although less ideal in certain respects, appear to have a place in the treatment of this disease Two-stage procedures allow a wide dissection similar to that of the Miles' operation The chief objective of graded procedures is to give to the less fortunate cases the advantage of a wide dissection without exposing them to risks which they may be unable to withstand Of the two-stage procedures, we prefer the Lahey technic Two-stage resections are preferable when dealing with badly infected and markedly stenosing tumors in patients who require

abdominoperineal operations, but whose general condition is not the best, and who might be classified as medium and poor surgical risks The first stage, which is the minor of the two operations, exerts but a moderate strain upon the patient. It is seldom more than an abdominal exploration with the construction of a simple colostomy The first operation, however, seems to lessen the possibility of, or raise the resistance to, pelvic infection at the time of the second-stage procedure, thereby lowering the operative fatalities due to pelvic peritonitis The interval between operations, usually four or more weeks, permits a lessening of the tumor infection and a recognizable improvement in the general condition of the patient

Two-stage procedures are, at times, of value when dealing with advanced disease when the surgeon, after exploration, has real difficulty in determining whether or not the patient should be subjected to radical operation Under these circumstances, one may plan a two-stage procedure and do the first stage at this time. If the patient shows the usual improvement, the second operation can be completed However, if the patient fails to pick up, and continues to lose weight and strength, these factors are a fair indication that the condition is inoperable Although such patients may survive the second operation, the final results are seldom satisfactory, as practically all cases continue to follow the downward decline The few postoperative deaths which have occurred with our two-stage procedure, and those patients who have done very badly after the second stage, were those who failed to show a real improvement after the first operation

Abdominoperineal operations are gradually becoming more popular In our clinic, a much higher percentage of patients are now being operated upon by this method than five years ago Moreover, there is a gradual trend to the one-stage procedure Whether one-stage or graded procedures are employed will depend upon the operator and the class of patient that he is called upon to treat In the past, these radical types of resec-

tions were often avoided because of the high operative mortality that resulted from their use in the earlier years. The operative mortality in these resections, although higher than that of perineal extirpation, is being gradually reduced. In a small series of 90 cases, we had an operative mortality of 13.3 per cent. Ten patients were operated upon over five years ago. Seven of these survived the five-year period and 6 of them are now alive and well.

Perineal resection or extirpation of the rectum for cancer has been in use for over a century. Its popularity is largely due to the low operative mortality. Consequently, this method is most ideal for the aged and those patients who, because of poor physical condition, must be classified as poor surgical risks. The disadvantage for routine employment is the high percentage of local recurrences. This, undoubtedly, results from the limited dissection of the invaded lymphatic channels and adjacent tissues, especially when the tumor is situated high in the rectum. If the disease, at the time of operation, is in the early stages, the results obtained should be equal to that of any other surgical method. When the disease is widespread and beyond the reach of dissection, the results can be of only a palliative nature, rather than a longstanding clinical cure. This type of resection is most ideal for poor surgical risks with tumors situated in the mid or lower rectum.

Perineal resections may be carried out with or without abdominal colostomy. The construction of a preliminary abdominal colostomy permits exploration of the abdominal cavity to ascertain the extent of local or metastatic disease. Perineal resection without preliminary colostomy denies the surgeon the advantages of an abdominal exploration and places the artificial anus in the perineum near the original site of the anal canal, a location greatly preferred by a few patients. In the majority of perineal resections we have employed a preliminary colostomy, but in those patients who refuse an abdominal anus and who are very obese, the resection has been done without pre-

liminary operation. In all cancer cases the dissection, whether perineal or abdominoperineal, should be as wide as possible in order to include the condemned adjacent tissues and infected lymphatic channels. Artificial openings, whether in the perineum or on the abdomen, are cared for very satisfactorily and without any great annoyance by patients who are free of disease. The majority carry on their routine occupations without any recognizable handicap.

The results of perineal resections are frequently inferior to those of abdominoperineal resections, other factors being equal. In a series of 120 patients subjected to colostomy and perineal resection, there was an operative mortality of 5 per cent. The majority of these patients received preoperative irradiation. Sixty-one patients were operated upon over five years ago with a five-year survival of 47.5 per cent.

Careful preoperative preparation and postoperative care are essential for good surgical results. All patients should be under observation for at least one week before operation. The colon is thoroughly cleansed, as it is usually in a very toxic condition, by the daily use of saline cathartics and colon irrigations. Preliminary high caloric diets are of value for patients who require building-up, and may be supplied with vitamins, iron, liver, etc. A diet of carbohydrates, sugar, and fruit juices is preferable for a period of five to seven days preceding operation. Patients running elevated temperatures should be carefully investigated as to the cause of the temperature. Oftentimes, it is wise to delay operation for a time because of this factor. Rectal cancer seldom produces an elevated temperature unless the disease is of a highly malignant type or harbors a local abscess. Investigation of the prostate is advisable in elderly males who give a history of nocturia. Examination frequently reveals a prostate that is best treated or removed before operation is undertaken. Fluids are given freely for at least five days, and are supplemented by intravenous injections of glucose for two or three days be-

fore operation Direct blood transfusions of 500 to 700 cc are administered routinely prior to beginning operation

Postoperative Care

Sedatives are employed freely for the first forty-eight hours Body fluids are restored by hypodermoclysis and intravenous injections of glucose and saline Blood transfusions are used when indicated Male and female patients are catheterized every six to eight hours Frequent catheterization appears preferable to the use of retention catheters The perineal wound should be inspected frequently The irrigation of these wounds, after the seventh postoperative day, adds to the comfort of the patients The value of sulfanilamide and neoprontosil in avoiding fatal infections is still not fully determined Further time will be required to evaluate the usefulness of these drugs in rectal resections

Radiation Therapy

Radiation therapy has proved to be of value in the treatment of rectal cancer Radium and roentgen rays may be employed as an individual method, or they may be combined with radical surgery Radiation therapy alone is most suitable for the early lesions The earlier the stage of disease, the greater are the possibilities of complete eradication and long-standing clinical cure It is the treatment of choice for many cancers measuring 4 cm or less in diameter In this selective group the results are equal, if not superior, to those of radical resection Medium and large cancers may also be treated by this method but the results are inferior to those obtained in treating tumors of smaller size The chief advantages of successful radiation therapy in the early lesions are (1) that patients avoid surgical operation, (2) they avoid long periods of hospitalization, and (3) they retain a normally functioning rectum Local and constitutional reactions following adequate use of the physical agents in small lesions are practically nil

Radiation therapy, when used alone to provide clinical cure, consists of external

applications of roentgen or radium rays, administered about the pelvis, through six or seven portals of entry Following the external treatments radon is applied either in the form of gold radon seeds implanted into the tumor mass or by surface applications If gold seeds are employed, the total dosage for sterilizing the cancer is administered at one time, while the total dosage of surface applications is given by divided daily dosage technic and extends over a period varying from fifteen to forty days The dosage required for eradication depends upon the size of the mass and the radiosensitivity of the cancer cells

The results of the above treatment in early operable rectal cancers are encouraging Thirty-one patients with tumors of about 4 cm or less in diameter, treated prior to March, 1938, are reviewed Irradiation, in 1 case, was a failure as operation was necessary one year later Five patients are dead Two died with liver metastases, without local recurrence, three and one-half and one and one-half years respectively after treatment Two died, ten and seven and one-half years respectively, after treatment, without recognizable rectal cancer One died, cause of death unknown, one and one-half years after treatment, with no evidence of disease at last visit An elderly woman of 71 years was lost track of after one and one-half years She had no evidence of disease at the time of her last visit The remaining 24 patients are alive and clinically free of disease Fifteen have been well for over three years while 9 have survived periods varying from five to ten years

In advanced operable disease, where surgical results are rarely good, there appears to be a real advantage in combining radiation therapy and radical surgery The preliminary external applications produce a favorable effect upon both the patient and the tumor The symptoms are reduced, the general condition is improved, and the tumor shows a marked decrease of ulceration, reduction in size, and often increased mobility Additional preoperative therapy is at times

advisable in the form of interstitial applications of gold radon seeds, which influence the outlying areas. When radon seeds are employed, operation is carried out seven to fourteen days later. Occasionally a few gold radon seeds are inserted, at the time of operation, into suspected tissue that cannot be removed. When there is a reasonable possibility that malignant cells remain, patients receive additional external therapy after convalescence. These treatments are repeated when thought advisable. While one cannot estimate, in a mathematical fashion, the value of the combined treatment, from clinical experience it would

seem that a higher percentage of clinical cures have been obtained and much greater palliation provided than in those cases where surgery alone was employed.

Conclusion

Early recognition contributes greatly to successful treatment of rectal cancer. Selective methods are preferable to any routine method in the treatment of this disease. The most radical forms of surgical dissection offer the greatest possibilities to patients in good physical condition. Radiation therapy in the very early lesions is at times the treatment of choice.

Correspondence

To the Editor

Looking over the JOURNAL of December 15, 1939, I want to express my full appreciation of pages 2237-38. I have been unable to see the value of *Health News*, it is filled with book reviews (entirely out of place) and idolizing of the "Nurses" and Mr Jones who thinks himself a wonder with his continually so-called idiomatic language. Once in a while he says some sound thing, but it could be much better condensed and expressed. Perhaps page 197 of *Health News*, November 27, 1939, has not struck you as it did me. Namely in "The Nurses of Tomorrow" I would like to know "where does the family physician come in?" I have heard it repeated over and over that the great value of the family physician is to be the "Counsellor of the family." Read it over!

EDMOND E BLAAUW, M D

Buffalo, N Y
December 20, 1939

To the Editor

In your editorial, "The Problem of the Arthritic," published in the January 1 issue of the State JOURNAL, you referred to my paper on Gold Therapy but misspelled my name. Kindly have it corrected.

The exact reference is "Gold Therapy in Rheumatoid Arthritis," Sashin, D., Spanbock J., and Kling, D H. Jour Bone & Joint Surg 21 723, 1939.

Very truly yours,

DAVID SASHIN, M D

New York City
January 5, 1940

The Editors regret this error in spelling and are glad to record the correction.

NATIONAL CONFERENCE ON MEDICAL SERVICE

The National Conference on Medical Service (formerly the Northwest Regional Conference) will hold its 14th Annual Meeting at the Palmer House, Chicago, February 11, 1940. All state medical societies have been invited to send representatives to the Conference, designed for the exchange of information on progressive medical service activities being conducted throughout the United States, and to discuss problems arising from the distribution of medical service to all classes. The Conference is not official nor political, is not connected with any other organization or committee, and its deliberations result in no resolutions or motions. It is informal, has no dues, bylaws, or formal organizational structure. The Conference has been successful because it

affords an opportunity for physicians who are officially associated with, or personally interested in, medical economics to exchange ideas.

The 1940 program, designed to give sound practical information, includes symposiums on group medical care and group hospitalization programs, the allocation of federal funds to the states, the Washington scene, effective public relations by physicians, and medical welfare programs (including the federal assistance groups, outdoor relief group, and medical and surgical care in hospitals).

Seventeen men, representing as many states in the Union, will be on the program of this one day meeting. It is anticipated that some thirty-five states will send representatives to the Conference.

ACUTE ABDOMINAL CONDITIONS

ROBERT F BARBER, M D , Brooklyn, New York

(From the Department of Surgery, Long Island College Hospital)

ACUTE inflammation within the abdomen is due to a variety of causes. One could list a large number of them and still add little to the understanding of the student unless such causes were correlated.

In starting the discussion it seems best for practical purposes to divide the abdomen into four general parts. The first includes the solid organs—the liver, the spleen, and the pancreas. The second comprises the gut, which includes everything from the cardia to the rectum. The third includes the ducts—the bile passages, pancreatic duct, the oviducts, and the uterus. The fourth comprises the blood vessels, with emphasis on those found in the mesentery.

Where possible, let us now apply trauma, infection, and obstruction to the four physical parts just described, and note the general results.

Trauma—A blow on the abdominal wall may produce a rupture of the liver, spleen, gut, or the pregnant uterus. It is well to note that the force of the blow may be so slight that the abdominal skin is not even bruised. Blood vessels are often ruptured by this type of injury. Intra-abdominal hemorrhage follows the rupture of the viscus as a natural sequence. This gives rise to constant pain as the outstanding symptom. In the gut, perforation is followed by hemorrhage, infection, and peritonitis. Penetrating wounds of the abdomen produce injury to the viscera depending upon the site of the injury. Hemorrhage and infection follow as in closed trauma.

Infection—The blood vessels and the bile passages of the liver serve as the carriers of infection. In the liver occur the solitary abscess from amebic ulcers of the colon and the milary abscesses from

blood borne bacteria. In the pancreas, from whatever source the infection may come, the final product is acute pancreatitis. In the gut, infection may result in an ulcer. The commonest types are the peptic and the colonic ulcers. The appendix is the most frequent seat of infection. Infection in the liver ducts and gallbladder is a common occurrence, and here we see all degrees of inflammatory changes from acute to chronic. The oviducts and the uterus receive infection from gonorrhea and abortions. In the abdominal vessels infection shows itself most often as a thrombophlebitis. The latter is seen very commonly in the more severe forms of appendicitis in the mesentery of the appendix. When it occurs in the mesentery of the bowel the clinical picture may be most obscure. To summarize for practical purposes, one may say that man's chief abdominal ills come from the appendix, the gallbladder, the peptic ulcer, the Fallopian tubes, and the pancreas. While the initial infection may be local and stay local, it often becomes diffuse. Following the diffuse stage the inflammation may again become localized either in the region of the original focus or elsewhere in the abdomen.

Obstruction—Stoppage of the ducts of the liver may be produced by calculi at any point, either intra or extra hepatic, by acute or chronic inflammation of the ducts, by tumors of the walls of the ducts, and finally by tumors pressing from without the walls. Stoppage of the veins of the liver occurs in thrombophlebitis of the radicals of the portal vein. It gives rise to the Zahn infarct. Stoppage of both the bile duct and the pancreatic duct often results from carcinoma of the head of the pancreas. In the gut tract,

*Read at the Annual Meeting of the Medical Society of the State of New York,
Syracuse, April 25, 1939*

stoppage may arise from without, as from the pressure of the neck of a hernial sac, from tumors lying adjacent to the bowel, and from bands running across the bowel in a constricting manner. Stoppage may come from within the lumen, as seen in pedunculated tumors, or from gallstones. Obstruction of the gut may come from lesions of the wall, as in muscular hypertrophy at the pylorus of infants, or scar formation of the pylorus following ulcer, or carcinoma at the pylorus or any part of the large bowel. Volvulus and intussusception produce stoppage by methods which need no amplification. In the oviduct and uterus, obstruction is caused by the growing fetus. Rupture is common in the oviduct and not uncommon in the uterus itself. Obstruction of the blood vessels gives rise to mesenteric thrombosis, thrombophlebitis, and infarcts.

Although this casual covering of the entire abdominal cavity is reasonably complete, one must add to the picture the acute abdominal history, which often accompanies angina pectoris, or the acute acidosis of diabetes. Slight fever and leukocytosis confuse the physician. The pain is often referred to the upper quadrants. Many a gallbladder has been removed (it may even have contained calculi) during an attack of angina.

The most important symptom for the clinician to consider is pain. The more extensive becomes his experience the more he will be impressed by the fact that pain is the only constant symptom in acute abdominal lesions. For this reason one should study with great care the onset, the character, the duration, and the location of the pain. Trauma, infection, and obstruction will each give rise to many modifications of the pain picture. The clinician will recognize by his experience the finer shades of the story. The pain of inflammation, for instance, is constant but varied in intensity. The pain of trauma or obstruction of the bowel is likely to be regularly irregular, with peaks of intensity which are due to peristalsis. The pain of perforation is very severe and shock producing. The pain of sudden

onset should be associated with tragedy.

Pain is absolutely subjective and for this reason the physician must school himself to interpret pain in terms of the psyche of the individual. Some take pain calmly and entirely without emotion. Some individuals highly sensitive to pain exhaust the superlatives of the English language in describing a moderate discomfort. In the presence of a real pain, symptoms in such persons are difficult to evaluate. Probably the greatest pain is associated with a perforated ulcer, impacted calculi in the biliary passages, and acute pancreatitis. Often the localization of pain will prove disappointing. In the early hours it will center about the navel. At this time the patient will be in such distress as to give little information on the locus of the offending structure. After the early hours have passed the truth may become evident.

The duration of pain is important as it indicates a progressive process, either increasing or diminishing. Sudden subsidence of pain suggests colic or stone. Tenderness holds the second place in importance in symptomatology. By palpation one may elicit the quadrant associated with the greatest inflammatory reaction. Even though there be a generalized inflammatory process this may hold true. The source of the infection will be found in the most tender quadrant.

The sign of Morris (i.e., tenderness on either side of the umbilicus) has proved of considerable value. In the female when the sign is bilateral it often points to pelvic inflammatory disease. But here again, one must remember that a bilateral positive sign is always present in diffuse peritonitis. A right-sided positive sign in the male indicates that we are confronted by a lesion of the gallbladder or the appendix. In a similar condition in the female one must add, as a possible lesion, infection of the right tube or ovary.

Nausea and vomiting are important symptoms because of their frequency. They are not of sufficient consequence to prove of great value in arriving at an opinion. The same may be said of the

white cell count in the blood Here, too, the experienced clinician will not be swayed from his diagnosis by a cell count which is out of harmony with a well-founded impression

In every abdominal calamity the careful clinician will include a pelvic or rectal examination By this means unexpected gynecologic accidents will not be overlooked. One must keep in mind that a ruptured Fallopian tube, torsion of an ovarian cyst, or perforation of the uterus are still common causes of abdominal tragedy

The x-ray is a modern diagnostic aid By this we do not refer to the more elaborate radiologic procedures, but merely to what is known as the flat plate There are at least five useful facts that may be learned from the x-ray film Distention of the large bowel is seen by its location, and of the small bowel by the typical stepladder-like cross markings Fluid, either diffuse or circumscribed, may be detected by the haziness of the gut outline and the loss of muscle markings Free gas in the belly is noted most often just under the right edge of the diaphragm, usually indicative of a ruptured viscus Enlargement of the solid organs is easily noted by their shadows Calcium containing bodies are at once noted Here the gallstone and the renal stone come into view The former may even be detected in the middle of the small intestine as a cause of stoppage.

When one realizes the similarity of the pictures that may be produced in the patient by a great variety of intraabdominal accidents, it becomes mandatory that a practical means be found for clarifying the picture. After all the facts have been gathered pain is still the most important single factor One might say that pain is the only constant symptom Pain is common to so many conditions that are not surgical that even with extensive experience there is a liberal percentage of error in diagnosis The surgeon will often be compelled to proceed on the one symptom of pain as the final arbiter of his action Repeatedly there will be borderline cases which demand a

finer judgment than he is capable of giving even with an extensive experience Here one should be guided by a philosophy which is definite, practical, and founded on experience It may be summed up in that oft-quoted aphorism "in doubtful abdominal cases it is better to go in and be wrong than to stay out and be wrong" Lest anyone should feel that this is advocating a radical attitude in favor of operation, we temper the extreme with another point of view In inflammatory abdominal conditions, which come to the surgeon at a late stage, where the patient's abdomen is greatly distended, where paralysis of the bowel is apparent by the stethoscope, and where the pulse is rapid and the temperature high, we believe that such patients have passed the stage where operation is advisable Under conservative supportive therapy such patients may and do recover, sometimes completely, sometimes with a residuum that needs operative treatment Until such a stage has been reached we consider these desperate cases to be "too late for an early operation and too early for a late operation"

In closing, a few words should be said about the distended abdomen Today we know that the gut becomes paralyzed and powerless to contract because of the volume of gas that it contains Either obstruction or inflammation of itself is not a competent cause of paralysis of the bowel, because, in the presence of either lesion if the gas is removed peristalsis is re-established The principal offending gas is nitrogen, most of which has been swallowed and passed from the stomach into the intestine If this nitrogen can be removed, the patient's condition becomes much improved for any operative procedure. After operation has been performed and distention threatens, the treatment for decompression of the bowel is equally applicable for postoperative cases as it is for preoperative cases

We have managed the distention problem with four tubes

First, the Levine tube inserted through the nose into the stomach. Constant negative pressure by the Wangenstein

method empties the stomach of its gas and liquid contents. A substitute for this first tube is the Miller-Abbott tube which works on a similar principle of decompression. This tube is not limited to the stomach, but passes into the small bowel and, in selective cases, even through the large bowel and out of the anus.

The second tube is the tube inserted into the rectum. Through this, irrigation is instituted by the Harris method. These irrigations are fatiguing and we have found it best to use them intermittently every three or four hours for a period of not more than ten to fifteen minutes. Often large quantities of gas are removed from the bowel by this method.

The third tube is the one inserted into the vein to supply the necessary water, salts, and glucose to the exhausted blood stream.

The fourth tube is the tube which delivers a stream of oxygen to the patient in such percentage as to decompress the distended bowel through the respiratory apparatus. A few years ago such a claim would have been regarded with skepticism, but today, we know from both experimental and practical evidence, that this method of decompression by air supercharged with oxygen has been efficient. From practical experience we do not hesitate to recommend the method.

To cover adequately the diagnoses and treatment of acute abdominal conditions in the space of this talk is impossible. We have attempted to touch lightly upon a few of the highspots of etiology, diagnosis, and treatment. We trust that our conclusions may be of some help to the physician who is confronted with an individual case that tries his judgment.

CLASS OF 1900 COLLEGE OF PHYSICIANS AND SURGEONS

The class of 1900 College of Physicians and Surgeons will hold a dinner at the New York Athletic Club on Monday evening, February 12 (Lincoln's birthday), to celebrate the fortieth anniversary of graduation. Not only will members of the class be present but also their sons and near relatives who have taken up the profession.

The notice sent to members urges all to attend, and suggests the slogan "Let life again begin at 40." The president of the class is Henry S. Patterson and the secretary is Theodore J. Abbott. The cost is five dollars and should be mailed to the chairman of the committee, Dr. Edmund P. Fowler, 140 East 54th Street, New York City.

ARCH FOE OF YOUTH

Over half the tuberculosis deaths in the United States occur in the age period 15 to 45, the main ages at which the individual is economically most productive and socially important to his family and the community. Tuberculosis strikes down those who are young and those in whom their elders have invested long years of cherishing care. This peculiarity, that it kills in the young adult years, makes tuberculosis a far greater social evil than those illnesses which take lives at later years when family responsibilities are less.

Although tuberculosis is the seventh leading cause of death at all ages, it ranks first in number of deaths from fifteen to forty-five years. In 1937, of the more than 250,000 deaths from all causes in this age group, tuberculosis accounted for 15 per cent, heart disease 11 per cent, pneumonia 9 per cent, cancer 6 per cent, kidney disease 4 per cent, cerebral hemorrhage 2 per cent.

Tuberculosis creates the greatest havoc among those least able to afford prolonged illness and results in a lowered standard of family life. Statistical studies show that the highest tuberculosis rates are found among the lower economic groups. If the patient is a dependent, it means hardship to the parents to bear the heavy expense of prolonged periods of invalidism. The tangible effect is reflected in the fact that there is a curtailment of earning power during the years when under normal conditions this earning power should be greatest. For those in the younger age group it brings about a drastic alteration in the manner of living, as the entire social aspect of life must be abruptly reversed. Preventable tuberculosis deaths among young people are a devastating and unnecessary blow to social morale.—Anthony M. Lowell, Assistant Statistician, New York Tuberculosis and Health Association.

SEROLOGIC TESTS AS AIDS IN THE DIAGNOSIS AND PROGNOSIS OF SYPHILIS

AUGUSTUS B. WADSWORTH, M.D., Albany, New York

(Director, Division of Laboratories and Research, New York State Department of Health, Albany)

IT is largely owing to your interest and support that the practicing physicians have at their command a laboratory service throughout the state, exclusive of the Greater City of New York, that is unique in the extent and standards of work. State and county medical societies have collaborated with the central laboratories in Albany toward developing a system of local approved laboratories for districts of the state that provides service for more than three quarters of the population, exclusive of the Greater City of New York. A policy of decentralization with close collaboration has thus been possible, and, during the past twenty-five years, standards of personnel and service have been advanced so that, in the future, diagnostic tests will be performed only in laboratories under a director who, in addition to graduation in medicine and eligibility for license to practice in the state, has an adequate knowledge of bacteriology and pathology and four years of postgraduate training and experience in these and related medical sciences. This local independent laboratory service supplemented by the central state laboratories, is now serving the physicians of the state far more effectively than would be possible through any expansion of the central state laboratories. The physician at the bedside needs the laboratory close at hand in order that he may give the technical experts complete information in regard to the individual case and receive expert advice concerning the results obtained in any examination. The physician must make his diagnosis in the light of complete information. A laboratory report should not be accepted as a diagnosis. It has always been our policy to submit the actual results obtained. A re-

port of "positive," "doubtful," or "negative" which connotes a diagnosis may be quite misleading.

An approval is now issued for the bacteriologic, serologic, and pathologic examination of specimens. The approval is voluntary, issued at the request of the laboratory on fulfilling the requirements of the Law and Sanitary Code. The local laboratories have formed a New York State Association of Public Health Laboratories which meets twice yearly and through its council offers advice and counsel to the Division of Laboratories and Research as to ways and means of improving the service that is rendered physicians and health officials.

The foregoing outline of the system and principles of policy and procedure is a necessary introduction to any consideration of the branch of the service that I wish to present to you in particular—namely, the serologic tests for syphilis. Although serologic tests are based upon the reactions of immunity in the tissues, their diagnostic significance is only in varying degree specific depending upon the character and scope of the test. The significance of the results must depend upon the clinical information available in each individual case. The serologic tests in gonorrhea are so far from specific in their present stage of development as to be unreliable or misleading unless interpreted in the light of the clinical history and diagnosis. The serologic test of agglutination for typhoid fever, as you all well know, is specific only when the degree of the reaction, the titer, is taken into consideration and the history, character of the present illness, or previous vaccination are known. The specific reactions underlying the serologic tests for syphilis

*Read at the Annual Meeting of the Medical Society of the State of New York,
Syracuse, April 26, 1939*

are not known and it is remarkable that the two tests—complement fixation, on the one hand, and, on the other, precipitation—are as specific as practical experience with them during the past twenty years appears to have established. Both forms of tests require the most careful standardization or adjustment of the reagents in order to safeguard against error.

Optimal proportions must be observed throughout in order to obtain accurate results. The early tests were those of complement fixation, and this method continues to be capable of the most accurate and sensitive adjustment, although the precipitation tests, when accurately standardized, now approximate it closely and, for reasons of expediency, in many laboratories have supplanted it. But serologists in general do not consider it safe to rely upon a single precipitation test and many, in actual practice, use several of them.

From the beginning, approval in New York State has been limited to complement fixation. There has never been any restriction as to what additional tests might be used in the local laboratories. This standard has been justified by the practical results that have been obtained in the central and local laboratories during the past twenty years. Moreover, it has provided a sound basis for the comparison of different methods and for the improvement in the serologic aids to the diagnosis of syphilis. Finally, it has led to the recent important development of a quantitative method of titrating the specific activity of the serums which is only at present practicable by a method of complement fixation. The quantitative methods have been under investigation for a number of years at the central laboratory and are practical adaptations of complicated procedures that were developed to determine the antigenic action of the lipides—cephalin, lecithin, and cholesterol. The present quantitative method has now been used two years by the central laboratory. Recently it has also been adopted in two of the local laboratories with satisfactory results.

Directors of six additional laboratories are arranging to do the work.

In 1927, six laboratories collaborated in a comparative series, reporting the results with the approved complement fixation methods and also additional precipitation methods that they had done in comparison with the complement fixation. The fact that complement fixation provides the most accurate and reliable method as compared with precipitation is clearly supported by the results of this series in 1927. In a recent comparative series, twenty-three of the approved laboratories have just submitted the results of their tests and, in this series also, the fact that complement fixation is capable of the most accurate and reliable standardization is supported by these results, but the difference in the two methods appears to be less today than twelve years ago.

The progress that has been made is reflected in the reports of Dr. Ruth Gilbert who has served as referee on the Serologic Tests for Syphilis for the Laboratory Section of the American Public Health Association for the past sixteen years. The practical studies and the research in the central laboratory have been maintained in close touch throughout the development of this work.

During the past twenty years knowledge of serology in syphilis as in other diseases has advanced materially. This is very strikingly illustrated by the results of comparative series of tests in this country and abroad. The evaluation of a comparative series of serologic tests should be based on fundamentally sound serologic principles. No serologic test has 100-per cent specificity. Claims for 100-per cent specificity are only misleading. The accuracy of any evaluation is limited by the accuracy of the data upon which it is based and any abridgments of the fundamental information, as the use of broad classifications, may sacrifice a part of this accuracy. This appears to be considerable when the results of serologic tests are reported "positive," "doubtful," or "negative" as prescribed by the United States Public Health Service in its study of comparative tests, especially since no

generally accepted basis exists for the classification. From the standpoint of aids to the clinician in diagnosis, the zone of the doubtful reaction may be conservatively broad or so narrow as to have no significance and to be definitely misleading. The doubtful zone is possibly the most important in any analysis of the practical value of serologic tests. Yet it has been neglected in the evaluation of these Federal series. Under these conditions, ratings based upon 100-per cent specificity and percentage of "positive" reports are not only open to serious criticism but reflect on the relative efficiency of the so-designated "control tests"—those of Kolmer, Kahn, Kline, and Hinton—which should be considered in relation to present-day standards of serology and in the light of what is possible. Not all serums from patients with a syphilitic infection react, and reactions may occur when no evidence of syphilis can be found. Finally, in rating percentages of specificity or sensitivity, apparently no account has been taken of the positive reports by the "control" laboratories on specimens of very slight activity or of negative reports on the serums of well-marked activity from cases of syphilis that had little or no treatment. If such a system of rating reflects on the "control tests," it may also reflect on or obscure the record obtained by some of the other laboratories.

Personally, I have reviewed only the results reported by the "control" laboratories, but it is obvious that the consensus of evidence in these reports indicates approximately—excluding instances of prozone effects—the true result, not necessarily from the standpoint of diagnosing syphilis but of what could reasonably be expected of a serologic test in the present stage of our knowledge. The consensus of these reports also corresponds with the clinical data. No marked discrepancies occurred with all of the tests but no single test was free from them, and the tests which had the highest percentages of sensitivity, namely, positive results with specimens from syphilitic cases—those of Kline and Hinton—had also the greatest

number of marked discrepancies. The results reported by Eagle in the 1938 series varied to an even greater extent. It is only by comparison with the results of the quantitative titration of the activity of the serums that further analyses, such as have been reported by Mrs. Maltaner,¹ associate referee with Dr. Gilbert, can be made of these discrepancies. That they are in the nature of prozone effects is suggested by the similarity of the reports, together with the clinical data, but comparison with the titers of the serums affords convincing proof.

The new quantitative test has been in practical operation in the central laboratory in Albany since April, 1937. Experience during the past two years has established it as a practical method—so far as we are able to ascertain, more accurate and reliable than previous methods. Moreover, it provides a sound scientific basis for further advances not only in the technic of determining the titer but also in evaluating the sensitivity and specificity of the antigens. In conformity with our policy of reporting the actual results of laboratory tests to the physician, the titers to one decimal have been reported. Obviously, the fractions on higher titers are of little or no significance and may connote a greater degree of precision than can be obtained with the technic at present, but they are important with the very low titers, because they are within the limits of the average technical variation. In the vast majority of cases the discrepancy between duplicate determinations is less than 25 per cent and is usually less than 8 per cent. Further study, now that an accurate technic of quantitation is available, should establish more accurate methods of preparing and standardizing the reagents, since it is possible to determine the factors that give rise to variation in the exceptional instances that have always occurred in both forms of test—complement fixation and precipitation. The activity of the serum in the course of infectious disease is well known to fluctuate, and this fact must be taken into account in evaluating the significance of any series of tests made at intervals in

the course of the disease or in studying the effect of treatment. Experience with the quantitative determination of activity in tuberculosis, for example, indicates that, in general, the fluctuation in titer corresponds to the activity of the tuberculous process, whether or not this is also true in syphilis may be determined, as information with the new test is obtained with further study of this disease. Despite the variation, it should be of definite practical value to the physician in both diagnosis and prognosis. An individual report is obviously not of much prognostic significance, but with repeated tests, the titers, in general, must be indicative of increase or decrease in the activity of the serums under treatment or in the course of the disease. For example, the fall in titer of early cases under treatment is prompt and marked in comparison with that of late cases of the disease, in which the infection has become established. Possibly it is the most reliable indication of the results of treatment and thus of prognosis. Certainly it is one of the most reliable signs of improvement in the condition of the patient. Certain syphilologists contend that a titration of the activity in the patient's serum is not of practical importance, but these syphilologists proceed with treatment by prescribed formulas which, by and large, in the majority of cases have proved effective or safe. But this does not apply to careful clinical analysis of the treatment of the individual case, and it is difficult to believe that even experienced syphilologists might not find information concerning the changes in the activity of the individual patient's serum of practical value.

With these trends, it seems to me that the great opportunity for private practice in comparison with regimented, prescribed formulas lies in taking advantage of all the refinements that medical science has developed as aids to the practice of medicine. Certainly, if one turns to the patient's chart of a modern practitioner, one finds recorded in detail the data indicating the changes that are taking place in the tissues during the course of the disease and under treatment.

I am convinced that physicians will find in these recent advances in the serologic test for syphilis definite practical aids to diagnosis and prognosis, and that, as experience with the new methods accumulates, it will clarify and stress the fact we all know but so often forget, namely, that the diagnosis should not be made in the laboratory but by the physician in the light of his clinical knowledge of the individual case.

Discussion

Dr. Girsch D. Astrachan, *New York City*—Any procedure or new technique which may help to clarify various problems in the field of serology, diminish the number of errors, remove different uncertainties of the diagnostic significance of various tests, should be welcomed by every clinician who deals with practical questions of the diagnosis and prognosis of syphilis.

The new method described by Dr. Wadsworth gives us a quantitative evaluation of the specific activities of the patient's serum. This titration with its more accurate determination of the changes in the serum reagin content may be of great practical value.

1. Cases of conflicting serologic reports or cases with doubtful reactions may constitute a perplexing problem for the clinician. If the history is negative, the tests have to be repeated several times and in various laboratories. Sending the blood to several laboratories and receiving many answers, often conflicting, may increase the confusion and multiply the difficulties of interpretation. In such cases a quantitative method may be of great help.

2. Serology of the newborn. It takes several weeks and sometimes even longer, with the routine serologic procedures, to make a definite diagnosis on the newborn. The quantitative method, performed at weekly intervals, may help to establish or refute the diagnosis of congenital syphilis in the newborn, in a much shorter period of time, by showing a gradual increase or decrease in the titer.

3. The gradual increase of the titer, shown by frequent tests, may also be of considerable value in the diagnosis of some cases of primary syphilis.

Efficacy of Therapy—We know of several types of syphilis in which a biologic or complete cure is possible. The large majority of early

cases, and a smaller number of early latent, and early congenital cases belong to this group. The efficacy of the treatment can be measured mostly by prompt changes in the blood serology.

If the tests are done by the routine method, nothing is known of the gradual response of the serology until the positive reaction changes to doubtful or negative, and this generally takes at least eight to ten weeks, and often much longer. With the quantitative method, however, we may determine the effectiveness of the therapy on the serology a few weeks after the institution of treatment.

Wassermann-fast Cases—The cause of seroresistance is not established yet, and while some believe it is due to persistent foci of spirochetes and progression of the disease, others consider it only a manifestation of persistent immunity. When discussing the prognosis of these cases, we have to consider the duration of the disease, the age, and the sex of the patient.

The seroresistance in a case of an elderly man with a history of infection of twenty to thirty years' duration, is of little significance. On the other hand, a young man with an early or early latent syphilis with a resistant serology presents a more serious problem. He may develop recurrences and other signs of progression of the syphilitic infection. A woman with latent syphilis may give birth to congenitally syphilitic children. Treatment, especially during pregnancy, is of paramount importance. The quantitative method by revealing even the slightest changes in the serology will be of great value to us in showing the efficacy of treatment in seroresistant cases. I would also like to say a few words about the so-called nonspecific serologic reactions. Cases of false positive and false doubtful reactions are found in serums of tuberculous donors (6 per cent). Fifty-three cases of nonspecific Wassermann and Kahn reactions in cases of pneumonia, bronchitis, herpes, tonsillitis are reported by Krag and Lonberg. These reactions may be quite misleading and may lead to the erroneous diagnosis of early syphilis. I observed 11 cases of nonspecific weakly positive Wassermann and Kahn reactions among pregnant women. I would like to hear from Dr. Wadsworth about the problem of nonspecific reactions and the possible way of clarifying this question.

Dr. Ernest Witebsky, *Buffalo, New York*—I believe that the expression "quantitative titration" would require some further definition and explanation. So far, the titer of the serum is defined as the smallest amount of serum (or the highest dilution) that would give a certain reaction under certain experimental conditions. In the investigations of Dr. Wadsworth and his associates, however, the amount of complement used rather than the titer of the serum under investigation is determined. In the field of precipitation tests a somewhat similar but by no means identical procedure was tried by Vernes. This French author, whose reaction is used on a large scale in France, determines by means of a nephelometer the strength of the reaction according to the degree of cloudiness obtained.

Inasmuch as the main importance of the Wassermann test is considered to be a diagnostic one, the quantitative titration of the serum in positive cases is somewhat neglected. In the case of examination of spinal fluid, however, the quantitative titration is considered of value for differential diagnostic purposes. Positive reactions are obtained in higher dilutions of spinal fluid from patients with general paresis rather than in tubes, where the antibody titer is usually very low. I feel, therefore, that especially for the examination of spinal fluid the elaborate methods developed by Dr. Wadsworth and Dr. and Mrs. Maltaner will prove to be very significant. The best thing to do, however, for diagnostic purposes, I believe, is to combine complement fixation tests as well as precipitation tests. Even when the best methods available today are used, contradictory results are not infrequently encountered. The constant occurrence of those discrepancies require cautious interpretation on the part of the clinician and should not be considered negligible, especially as far as the diagnostic phase is concerned. While I consider it rather difficult to rely on complement fixation tests alone, or on precipitation tests alone, I feel that the new method introduced by Dr. Wadsworth represents an important step forward in the development of serologic technique. The relatively constant values obtained by that method is really amazing to everybody engaged in serologic work. I am sure, therefore, that the new method developed in Albany will prove to be very useful not only for the serodiagnosis of syphilis, but for the serodiagnosis of tuberculosis and gonorrhea.

THE ROLE OF THE ENDOCRINES IN DERMATOLOGY

JOSEPH JORDAN ELLER, M D , and LLOYD H KBST, M D , New York City

CERTAIN dermatoses have been proved to be associated with glandular dysfunction. In some, the endocrines may play a part in association with other etiologic factors. There is another group of dermatoses whose etiology has not been proved but is believed to be due to some endocrine disturbance. The relationship of the hormones to the vegetative nervous system and the vitamins is now recognized. Murlin states¹ "We are able to demonstrate startling similarities, not only between the various hormones themselves, but also between hormones and vitamins, structurally and functionally." Furthermore, it has been shown recently that the adrenal cortex is the main storage organ of vitamin C.

It is difficult at times to determine which gland is the center of a primary disturbance and which is secondary. No one gland acts independently. They are all woven into a complex interrelationship. Thus we may observe a polyglandular etiology in many diseases. It must also be recognized that the improvement observed with the use of a glandular extract does not prove the etiology of that disease. The effect may not be due to specific substitution therapy, but rather to the action of the drug.

Pineal Gland—The pineal gland has not as yet been assigned a recognized function.² In dermatology there is no definitely known cutaneous disturbance which results from its dysfunction, excepting possibly certain pineal tumors which are associated with hypertrichosis.

Pituitary Gland—The pituitary gland has a very complex structure and its proved interrelationship with other glands makes it difficult to isolate as the sole or primary offender in a particular disease. Almost everyone of the endocrine glands has been mentioned in association with

scleroderma. Posterior lobe dysfunction may be a factor in this disease, as evidenced by Oliver and Lerman³ in their paper summarizing the improvement observed in 20 patients with scleroderma (morphea, linear, and diffuse types). They state, however, that this is probably due to the effect of the solution on the peripheral circulation rather than to any substitution effect. Exanthemas, gingivitis and stomatitis, and xanthomatoses occurring in Schuller-Christian's disease have been observed in persons manifesting a posterior pituitary dysfunction. There is no cutaneous disease proved to be the result of hyperfunction of the posterior pituitary.

Sevringhaus⁴ states that "A pigment controlling material has been found in animals, probably related to the intermediate rather than to the posterior pituitary lobe and has no demonstrated significance in human physiology." Recent observers⁴ believe that the pituitary gland may be the source of pigmentary alterations. A chromatophore substance has been found in the pars intermedia, posterior lobe, and adjacent areas in the wall of the third ventricle which stimulates the pigment bearing cells of cold blooded animals. The authors suggest that a similar hormone is elaborated by the human pituitary, which exercises a similar effect on skin pigment.

Anterior Pituitary—In acne vulgaris the consensus is that endocrine dysfunction, particularly of the anterior pituitary and gonadal glands, plays a leading role in the etiology and at times may be the sole cause of this condition. McCarthy and Hunter⁵ noted a complete absence of estrogenic substances in the urine of many patients with acne during various phases of the menstrual cycle. They also noted a deficiency in the production of

estrogenic substance in the blood of menstruating normal women who had an accompanying acne. They concluded that a deficiency secretion of the follicle ripening hormone may be the direct or indirect cause of one type of acne. However, treatment with gonadotropic and estrogenic substances proved without benefit in these cases. Coincidental with this they also came to the conclusion that thyroid dysfunction rarely shows any relation to acne. Alopecia prematura and hypertrichosis have been reported associated not only with pituitary dysfunction, but also with most every other gland. Results of treatment have varied and although most observers believe it has a definite endocrine relationship, there may be other factors associated with it, especially the sympathetic nervous system.

In any severe hypofunctional state of the anterior pituitary lobe such as in Simmond's disease, marked skin alterations are a distinct feature. The skin is coarse in texture. Due to lack of nutrition, the sweat and sebaceous glands may become atrophied, the result being lack of perspiration and especially loss of hair. Destructive nail changes may also be a feature. Rosenthal⁶ showed evidence of disordered pituitary function in one of his cases of striae atrophicae cutis. In Cushing's basophilic hyperpituitarism, the purplish lineae atrophicae, hirsutism, and a dry plethoric skin are seen, and in acromegaly, a diffuse thickening of the skin and a tendency to hypertrichosis and hyperpigmentation. Fibromas are sometimes seen. In all of these conditions, endocrine dysfunction is a proved factor in the etiology, and the associated cutaneous manifestations must be considered the same. It is noted⁶ that striae in young adolescents with obesity which lessens or disappears with maturity is probably due to a temporary endocrine upset.

Dermatologic manifestations associated with thyroid dysfunction are vague in many instances. However, in myxedema, the result of insufficient hormone production, there is present a dropsy-like swelling of the skin which is coarse, dry, and rough. There is a falling out of the hair

on the scalp and outer portion of the eyebrows (Hertoghe's sign) with a sparsity on other parts. A ribbon-like alopecia on the forehead and on the nape of the neck is considered to be characteristic. The nails are brittle, thin, and striated. Bat wing freckling is frequently seen on the face of cretins. This may indicate an associated involvement of the pituitary gland. In thyrotoxicosis, all the metabolic processes are increased resulting in skin manifestations and disturbances of hair and nails. The skin is thin, warm, and moist and may show pigmentation and dermatographism. Simple erythemas may occur. In scleroderma, postmortem findings sometimes show atrophy of the thyroid which explains the improvement, in some cases, from thyroid therapy. Pardo-Castello⁷ reported two cases of atrophy of the nails of the hands and feet. Smith⁸ states that Lurthlen observed that in animals deprived of the thyroid gland, all healing processes in the skin are retarded, and furthermore, the derma in such animals responds to slight irritation by the formation of scars and keloids.

Parathyroid Gland—The parathyroid gland regulates the amount of phosphorus and calcium in the blood, the excretion of these elements, and their deposition in or mobilization from certain tissues. The hormones share this responsibility with vitamin D.² In an interesting article based on the theory of keloid formation being caused by hypersecretion of parathyroid, Biberstein⁹ injected overdoses of parathyroid hormones into animals and showed a definite proliferation of connective tissue, so that muscle bundles disappeared at the site of injection and were replaced by firm infiltrations which remained and even spread after injections were stopped. Favorable reports have been noted by many authors^{10 11 12} with parathyroidectomy and parathyroid therapy in cases of scleroderma. Wolf states that the parathyroid hyperactivity is the initiating factor, osteolysis the intermediary step, and scleroderma the final result. R. Lenche, *et al.*,¹³ report a case of experimental production of a scleroderma condition in a rat with fragments

of cystic adenoma of the breast from a patient with scleroderma Cornbleet¹⁴ used parathyroid extract subcutaneously in 21 cases of lichen urticatus with improvement in almost all of them Pillsbury and Sternberg¹⁵ have observed similar results Wigser¹⁶ used parathyroid therapy with beneficial results in a case of urticaria of undetermined origin

Impetigo herpetiformis has been considered to be an endocrine disorder associated mostly with the parathyroid¹⁷ G Scherber¹⁸ has reported good results with parathyroid therapy in this condition as well as in psoriasis vulgaris pustulosa Plá and Martinez¹⁹ reported 2 cases of vitiligo improved by parathyroidectomy or ligation of the thyroid artery Rados and Rosenberg²⁰ state that there is a relation between blue sclera and hyperparathyroidism Calcinosis cutis and alopecia prematura have often been reported associated with parathyroid dysfunction

The *thymus* is only mentioned to state that up to the present, association with dermatologic conditions has not been proved It has been noted, however, that an individual with a hypertrophied thymus gland may have a transparent skin and silky hair In Timme's syndrome the skin is velvety and there is little or no hair Many years ago some authors thought that the thymus might have a relationship to psoriasis, but this was never corroborated

The cortex of the *adrenal* is known to be dependent upon the pituitary for its integrity Whether the cortex and medulla are functionally connected is only speculative The cutaneous pigmentation of Addison's disease, usually of the exposed parts, is known to be a definite part of cortical hypofunction The pigmentation also appears on the mucous membranes Pigmentation of the nails and fenestrations has been reported in this condition Certain adrenal cortex tumors alone or together with pituitary dysfunction may be an etiologic factor in Cushing's syndrome In cortical hyperfunction, hypertrichosis may be extremely marked on the entire body including the

dorsum of the feet The hyperpigmentation frequently seen in the diffuse type of scleroderma has been used as an argument that adrenal changes are a cause of the disease Hypertrichosis and many pigmentary disturbances are often associated with adrenal dysfunction, i e, the blanching of the skin in Froelich's syndrome and its darkening in acromegaly are usually considered to be due to associated adrenal changes Goldzieher states that the old women's beard with its coarse, black, scattered hair on the upper lip and on the chin is pathognomonic of cortical hyperfunction Allergy may result from cortical insufficiency as large quantities of vitamin C are stored in the cortex

Pancreas—The pancreas is a factor to be considered in cutaneous dermatoses There is a tendency for the prevalence of dermatophytosis on the feet of diabetic patients, probably the result of a hyperglycemia with the production of excellent media on which fungi and bacteria may grow Also associated with pancreatic insufficiency are furuncles and carbuncles and occasionally gangrene of the extremities Necrobiosis lipoidica diabetorum is usually associated with diabetes although it has been observed in nondiabetics Xanthochromia, a yellowish discoloration of the skin, is sometimes seen

Menstrual disturbances with their cutaneous manifestations, pigmentations of pregnancy (chloasma, linea alba, the perimamillary areas, vulva), herpes gestationis, alopecia prematura, alopecia areata, impetigo herpetiformis, hypertrichosis, and abnormal secretion of sweat and sebum are associated with dysfunction of the gonadal glands It is interesting to note that chloasma may occur in virgins as well as males In hypogonadism the skin may become wrinkled and appear as a brownish coloration Long, coarse hairs on the face occur in old age (geroderma) Herpes is often seen in association with menstruation and pregnancy Thaddea²¹ reports a case of Addison's disease complicating pregnancy and cites the relation of the suprarenal cortex to the gonads Kraurosis vulvae and senile vaginitis have been reported improved by

injections of estrogenic hormones. Physiologic experiments show that estrin has a marked action on skin and in particular on skin and mucous membranes of the genitalia, where it causes an increased growth of squamous cells and hyperemia of the deeper tissues. Foss²² states that of 8 actual cases of kraurosis vulvae all the patients who attended regularly and received adequate dosage were benefited. Davis²³ made stained biopsy specimens in cases of senile vaginitis before and after estrogenic therapy and so demonstrated that during six to eight weeks the atrophic epithelium had reverted to the normal state associated with active sexual life. Peters and Macheth²⁴ state "It is interesting that the most satisfactory method of treatment has been the combination of intravaginal and intramuscular therapy." The intravaginal therapy followed the observation of many biologists that certain harmonic effects are more easily obtained by local application of the hormone in a form which can be absorbed by the epithelium than by its parental injection. Dermatitis dysmenorrhoeica may be associated with or be independent of the periods.

Andrews²⁵ states that an observation of eunuchs, if correct, suggests that the factor for baldness may ordinarily be effective only in the presence of the testes and that the gonads certainly have an etiologic importance. Goldzieher is of the opinion that baldness never occurs in the eunuch or in the eunuchoid type.

Erythrocyanosis cutis symmetrica is considered an endocrine disturbance in which the skin changes are brought about by exposure to cold.

In their case of acanthosis nigricans, Grace and Schwartz²⁶ were unable to discover any definite evidence of endocrine disturbance and hold the hypothesis of endocrine dysfunction as an etiologic agent in acanthosis nigricans as unfounded.

It is recognized that tinea of the scalp after puberty is not common and that many cases have the tendency to clear up at puberty without therapy. The relation of allergy of the skin to the endocrines

and vitamins is a field in which much recent work has been done. The adrenal cortex is an important aid in the regulation of mineral metabolism and appears to be one of the factors responsible for allergy. In the later stages of hyperthyroidism where much of the calcium has been lost many allergic manifestations are observed.

Treatment will be mentioned here only to state that it is not without danger.²⁷ Many have reported untoward systemic and possibly local effects following topical applications of estrogenic hormones. They state that it has been proved such hormone absorption topically or parenterally can induce proliferation in the tissues, particularly in the genital tract, which in animals has resulted in the development of cancer. Zondek²⁸ has also shown that cutaneous applications of follicular hormones can be absorbed through the skin and produce marked systemic effects.

The Society of the New York Hospital Lewis Cass Ledyard, Jr Fellowship

The Lewis Cass Ledyard, Jr Fellowship was established in 1939 by a gift from Mrs Ruth E Ledyard, wife of the late Lewis Cass Ledyard, Jr, a Governor of The New York Hospital. The income, amounting to approximately \$4,000 00 annually, will be awarded to an investigator in the fields of medicine and surgery, or in any closely related field. This amount will be applied as follows: \$3,000 00 as a stipend and, approximately, \$1,000 00 for supplies or expenses of the research. In making the award, preference will be given to younger applicants who are graduates in medicine, and who have demonstrated fitness to carry on original research of high order. The recipient of this Fellowship will be required to submit reports of his work under the Fellowship, either at stated intervals or at the end of the academic year, and when the result of his work is published he will be expected to give proper credit to the Lewis Cass Ledyard, Jr Fellowship. The research work under this Fellowship is to be carried on at The New York Hospital and Cornell University Medical College. The fellowship will be available on July 1 at the beginning of the academic year. Applications for the year 1940-1941 should be in the hands of the Committee by the 15th of February. It is expected that the award will be made by April 1st, 1940.

Application for this Fellowship should be addressed to

TRIBORO HOSPITAL STAFF TO BE SELECTED

Dr S S Goldwater, Commissioner of Hospitals, announced yesterday the appointment of a committee to assist in the selection of a medical staff for Triboro Hospital, the new 500-bed hospital for tuberculosis now approaching completion, adjoining Queens General Hospital on Parsons Boulevard, Jamaica.

The Advisory Committee on medical organization consists of Dr Robert F Loeb, chairman, Dr I Ogden Woodruff, Dr Frank N Dealy, Dr Robert Plunkett, and Dr Carl Eggers.

Applicants for appointment to the Honorary Visiting Staff of Triboro Hospital are asked to submit their applications to the Commissioner of Hospitals.

The pathologist and roentgenologist for Triboro, among the few salaried medical officers in city hospitals, will be selected from Civil Service lists. The medical superintendent will likewise be appointed under Civil Service rules.

Members of the Honorary Visiting Staff in city hospitals are classified as visiting, associate visiting, assistant visiting, and clinical assistant visiting physicians. Directors of services are visiting physicians designated to act as directors for specified terms.

According to the rules of the Department of Hospitals, a visiting physician must have been in practice for at least eight years and if a specialist must have been identified with his specialty for not less than five years. Associate visitings must have been licensed to practice medicine for at least five years, assistant visitings, at least three years, clinical assistant visitings must have completed an internship in an approved hospital.

All appointees must be citizens of the United States and must be physicians of good ethical standing, licensed to practice medicine in the State of New York.

THE SPARING EFFECT IN POLIOMYELITIS*

GILBERT DALLDORF, M D , Valhalla, New York

(From the Laboratories of Grasslands Hospital, Valhalla)

THE biologic phenomena of vaccination and the use of immune serum have so far failed to provide means of preventing or treating poliomyelitis and the search has been extended to less orthodox means. Thus the experimental disease can be effectively prevented by nasal sprays. This method is well known and has been widely used. It is not commonly known that even after poliomyelitis is induced in monkeys it can be greatly modified. This may be done by infecting the animals with another disease, lymphocytic choriomeningitis. While such a method does not seem adaptable to the clinical treatment of poliomyelitis it deserves study and consideration for the light it may throw on poliomyelitis in particular and the virus diseases in general.

Before describing the effect of combination of the two diseases it will be useful to mention their characteristics. The poliomyelitis virus used throughout these experiments is known as MV (mixed virus), a pool of viruses derived from various human cases. It has been used in many laboratories over a long period and is thoroughly adjusted to the monkey. The intracerebral inoculation of 0.2 cc. of a 10 per cent suspension of pooled cord samples produces, as a rule, a uniform, fatal disease. The response is characterized by an incubation period of three days, followed by high fever and prostration within 72-96 hours. Death soon follows.

Lymphocytic choriomeningitis virus produces a much more varied, though usually less violent response. During our early experiments using virus from dog and ferret sources, the disease was benign, with few fatalities. The incubation

period is several days, followed by two weeks of fever of a typhoidal character subsiding slowly and often followed by subnormal temperatures. Virus that has been maintained by monkey passage produces a similar response except that the febrile period often terminates earlier by rapid lysis accompanied by extreme weakness, emaciation, and death. In our experience the mortality of uncomplicated lymphocytic choriomeningitis in the monkey has varied from 9 to 84 per cent depending on the source of virus and other factors.

The combination of these two diseases markedly modifies the outcome of the poliomyelitis. This we have called the "sparing effect" to distinguish it from other immunologic mechanisms. The features of the "sparing effect" are as follows:

1. *Time* is the most significant factor in determining the effect of lymphocytic choriomeningitis on poliomyelitis. This is shown by Table 1 in which a number of experiments have been collected. Thus, of 16 monkeys which from four to thirteen days previously were injected with lymphocytic choriomeningitis virus, 11, or 70 per cent, recovered from poliomyelitis. The mortality among the poliomyelitis controls was 100 per cent. If the lymphocytic choriomeningitis was given twenty-four to seventy-two hours before the poliomyelitis, but 50 per cent survived and if it was withheld until after the poliomyelitis appeared, only 30 per cent recovered. The stage of choriomeningitis in which the poliomyelitis is given therefore plays a determining role in the results.

2. The mechanism is not a matter of cross protection. Thus, also incorporated in Table 1 are the results in 4 mon-

TRIBORO HOSPITAL STAFF TO BE SELECTED

Dr S S Goldwater, Commissioner of Hospitals, announced yesterday the appointment of a committee to assist in the selection of a medical staff for Triboro Hospital, the new 500-bed hospital for tuberculosis now approaching completion, adjoining Queens General Hospital on Parsons Boulevard, Jamaica.

The Advisory Committee on medical organization consists of Dr Robert F Loeb, chairman, Dr I Ogden Woodruff, Dr Frank N Dealy, Dr Robert Plunkett, and Dr Carl Eggers.

Applicants for appointment to the Honorary Visiting Staff of Triboro Hospital are asked to submit their applications to the Commissioner of Hospitals.

The pathologist and roentgenologist for Triboro, among the few salaried medical officers in city hospitals, will be selected from Civil Service lists. The medical superintendent will likewise be appointed under Civil Service rules.

Members of the Honorary Visiting Staff in city hospitals are classified as visiting, associate visiting, assistant visiting, and clinical assistant visiting physicians. Directors of services are visiting physicians designated to act as directors for specified terms.

According to the rules of the Department of Hospitals, a visiting physician must have been in practice for at least eight years and if a specialist must have been identified with his specialty for not less than five years. Associate visitings must have been licensed to practice medicine for at least five years, assistant visitings, at least three years, clinical assistant visitings must have completed an internship in an approved hospital.

All appointees must be citizens of the United States and must be physicians of good ethical standing, licensed to practice medicine in the State of New York.

not exclusive of a quantitative difference in the immunologic responses, they suggest that the combination exerts no considerable effect.

6 The question naturally arises whether the action is mutual in that the poliomyelitis modifies the choriomeningitis as well as the reverse. There was no indication of this in the original experiments but at that time the choriomeningitis was relatively benign and the best yardstick of such an effect, the mortality rate, was lacking. In more recent experiments, in which the choriomeningitis alone produced a mortality rate of 83 per cent and the mortality rate among the poliomyelitis controls was 78 per cent, the mortality rate among various groups of the combination animals was 30, 42, and 50 per cent. In other words, there was some evidence that the effect was mutual, that the combination of the two diseases lessened the severity of each.

7 You will have noticed that mortality and not paralysis has been the criterion used in the tables. This has been done because of the nature of the disease in monkeys. In the present work the control animals with but rare exceptions have either developed a severe, rapidly fatal form of poliomyelitis or have been cases of "missed infection." In the experimental groups with high survival rates, many animals have recovered with paralysis of one or more extremities. All of these which we have been able to follow for several months have completely recovered function in their paralyzed limbs. Neither the experience of others nor our own controls make possible a comparison of these results with the behavior of monkeys not infected with choriomeningitis. The observation is made both to indicate the differences between the experimental and spontaneous disease and the difficulties in measuring the effects of treatment.

8 The "sparing effect," as I have described it,¹ is not an isolated observation. A similar effect of vaccination on whooping cough was described by John Archer in 1809.² In more recent times

a similar phenomenon has been rather extensively studied in potato virus.³ Hoskins,⁴ in 1935, reported experiments quite similar to ours. Hoskins, however, used different strains of the same virus, that of yellow fever. At the most favorable interval 18 of 23 monkeys survived while later only 9 of 25 survived. These experiments have been confirmed and extended by Findlay and MacCallum⁵ who demonstrated that Rift Valley fever likewise exerts a "sparing effect" on yellow fever. Various other references to a like phenomenon may be found, most of a casual nature.

It seems evident, therefore, that in the "sparing effect" we have an effective immunologic mechanism. Its virtue is that it is effective under conditions in which other means are useless. Its weakness is that it requires the use of a second pathogenic agent. Whether there are possibilities for good in this mechanism only time can tell.

Discussion

Dr. Orren D. Chapman, *Syracuse, New York*—Any addition to the knowledge concerning the mechanism of the virus diseases is always welcome. The experiments of Doctor Dalldorf and his co-workers at the Grasslands Hospital have contributed definitely to this knowledge.

(1) As a result of their early experiments they felt justified in concluding that the infection caused with virus of canine distemper had a sparing effect upon poliomyelitis in the experimental animal. Later they reported (November, 1938) that certain lots of their canine distemper virus were contaminated with the virus of lymphocytic choriomeningitis and further reported that the sparing effect in poliomyelitis seemed to be due to the latter virus.

(2) Today they have demonstrated more completely that the virus of lymphocytic choriomeningitis when injected into the experimental animal with a proper time relationship does ap-

TABLE 1—INFLUENCE OF TIME ON THE SPARING EFFECT

Time at Which the Lymphocytic Choriomeningitis Was Given	Number of Monkeys	Recovered	Results	Died
Three to five months before poliomyelitis	4	0		4
One month before poliomyelitis	2	0		2*
Twenty days before poliomyelitis	2	1		1
Four to thirteen days before poliomyelitis	16	11 (70 per cent)		5 (30 per cent)
One to three days before poliomyelitis	8	4 (50 per cent)		4 (50 per cent)
During the incubation period of poliomyelitis	10	3 (30 per cent)		7 (70 per cent)

Poliomyelitis controls for first two groups had a mortality rate of 100 per cent. Controls of last three groups had mortality rates of 87 to 100 per cent.

* Sacrificed on 30th day when condition seemed hopeless. Controls of this group all died in from five to fourteen days. Sparing effect believed present.

keys which had had lymphocytic choriomeningitis three to five months before poliomyelitis. All of these succumbed to poliomyelitis in typical fashion. Likewise immune serums have been found to exert no protective effect against poliomyelitis.

3 The response is not due to fever. Thus, of the 2 monkeys injected with poliomyelitis virus twenty days after choriomeningitis both were afebrile at the time of the second inoculation yet the "sparing effect" was distinctly present. In both animals the poliomyelitis was modified and one recovered. Various similar examples have been observed. Furthermore, the fever in the animals that recover is commonly less severe than in those that succumb, and characteristically is less severe than in uncomplicated poliomyelitis itself. It is, however, true that the period of greatest effectiveness roughly corresponds to the febrile period of lymphocytic choriomeningitis but this is probably true simply because the febrile response reflects the natural evolution of the disease.

4 The "sparing effect" is present during systemic infection. It is not, in the experiments included in the present discussion, a local effect but a general one. This is indicated by the fact that the two viruses may be given by dissimilar routes

TABLE 2—RESULTS OF REINOCULATING MONKEYS WHICH HAD RECOVERED FROM SPARING-EFFECT EXPERIMENTS WITH POLIOMYELITIS VIRUS

Number	Results of Original Experiment	Result of Reinoculation	Resistant	Susceptible

4	Paralysis	4	0	4
1	No paralysis			1*

* Recovered with paralysis. During original experiment had transient weakness of one leg.

and at sites distant to one another without modifying the results. This statement may not apply to intranasal infection.

5 The combination does not appreciably interfere with the independent immunologic responses to the two diseases. Neither does it heighten the response so far as the present evidence shows. Monkeys convalescent from combined infection are immune or susceptible to reinfection with poliomyelitis depending on whether or not their original attack was paralyzing. This is shown by Table 2. This is precisely what happens when recovered poliomyelitis controls are reinjected. Furthermore, monkeys that have experienced both diseases simultaneously develop an immunity to choriomeningitis as do choriomeningitis controls. After two months they are fully immune. Virus neutralizing antibodies are present in the serums of such convalescents (Table 3). While these results are

TABLE 3—IMMUNITY TO REINOCULATION AND PRESENCE OF SERUM NEUTRALIZING ANTIBODIES IN MONKEYS CONVALESCENT FROM COMBINED INFECTION WITH POLIOMYELITIS AND LYMPHOCYTIC CHORIOMENINGITIS

S indicates the guinea pigs surviving. The numerals indicate the day on which the pigs died.)

not exclusive of a quantitative difference in the immunologic responses, they suggest that the combination exerts no considerable effect.

6 The question naturally arises whether the action is mutual in that the poliomyelitis modifies the chorionmeningitis as well as the reverse. There was no indication of this in the original experiments but at that time the chorionmeningitis was relatively benign and the best yardstick of such an effect, the mortality rate, was lacking. In more recent experiments, in which the chorionmeningitis alone produced a mortality rate of 83 per cent and the mortality rate among the poliomyelitis controls was 78 per cent, the mortality rate among various groups of the combination animals was 30, 42, and 50 per cent. In other words, there was some evidence that the effect was mutual, that the combination of the two diseases lessened the severity of each.

7 You will have noticed that mortality and not paralysis has been the criterion used in the tables. This has been done because of the nature of the disease in monkeys. In the present work the control animals with but rare exceptions have either developed a severe, rapidly fatal form of poliomyelitis or have been cases of "mussed infection." In the experimental groups with high survival rates, many animals have recovered with paralysis of one or more extremities. All of these which we have been able to follow for several months have completely recovered function in their paralyzed limbs. Neither the experience of others nor our own controls make possible a comparison of these results with the behavior of monkeys not infected with chorionmeningitis. The observation is made both to indicate the differences between the experimental and spontaneous disease and the difficulties in measuring the effects of treatment.

8 The "sparing effect," as I have described it,¹ is not an isolated observation. A similar effect of vaccination on whooping cough was described by John Archer in 1809.² In more recent times

a similar phenomenon has been rather extensively studied in potato virus.³ Hoskins,⁴ in 1935, reported experiments quite similar to ours. Discussion

Dr. Orren D. Chapman, *Syracuse, New York*—Any addition to the knowledge concerning the mechanism of the virus diseases is always welcome. The experiments of Doctor Dalldorf and his co-workers at the Grasslands Hospital have contributed definitely to this knowledge.

(1) As a result of their early experiments they felt justified in concluding that the infection caused with virus of canine distemper had a sparing effect upon poliomyelitis in the experimental animal. Later they reported (November, 1938) that certain lots of their canine distemper virus were contaminated with the virus of lymphocytic chorionmeningitis and further reported that the sparing effect in poliomyelitis seemed to be due to the latter virus.

(2) Today they have demonstrated more completely that the virus of lymphocytic chorionmeningitis when injected into the experimental animal with a proper time relationship does ap-

parently induce modification of the disease poliomyelitis in the experimental animal. At this time I would like to congratulate Doctor Dalldorf upon his experiments.

The significance of these findings is, as yet, beyond one's comprehension. No one, at present, can prophesy the possible value of this work. It is tempting to speculate concerning the mechanism of this sparing effect, however, we must realize that speculation is dangerous in the light of our present ignorance concerning viruses in general. The lack of the demonstration of cross immunity and flowing immune substances would lead one to believe that this sparing effect is a blocking of cellular metabolism or cellular physiology such that the second induced infection cannot be spread by "perversion" of cellular physiology.

Dr James Denton, *New Rochelle, New York*—The immunologic mechanism which Dr. Dalldorf has described is interesting not only in connection with the diseases he has been studying but also from the obvious implications that similar relationships may be found between other virus diseases. A complete understanding of the factors responsible for this sparing effect might throw considerable light on the essential nature of virus diseases. There are obvious advantages in the study of a phenomenon that can be produced under experimental control.

Naturally, the first thing that suggests itself is the possible application of the phenomenon

to human cases of poliomyelitis. Poliomyelitis in man and in monkeys differ from each other in many important respects. The extreme rapidity with which the disease progresses in the monkey is unusual in the human disease, but does occur. The intervals in the time schedule which appear to be so important might be very different in man and more favorable for practical purposes.

There are many fundamental factors in human poliomyelitis which are still obscure. The pathogenesis is imperfectly understood. The prompt recovery of function in so many cases raises the question as to whether the nerve cells are permanently damaged at the outset or whether the harmful effects of the virus extend over a considerable time. Early complete loss of function very possibly masks progressive effects of the virus.

It is my understanding that chorionmeningitis virus has been used as a substitute for malarial therapy in France. Chorionmeningitis is generally regarded as a benign disease, but rather serious symptoms are said to have appeared in some cases. Apparently the only way to find out whether the virus may be of value in the clinical stages of poliomyelitis is by trial on human cases. A very serious difficulty arises here on account of the difficulty in making a dependable diagnosis of poliomyelitis in the early phases of the disease. Paralysis is necessary for a final diagnosis, and there are possibly errors even with this.

STOP TINKERING

Upheavals of tested institutions have ruined the continent of Europe. Liberties and freedom of enterprise of the individuals have been sacrificed on the altar of so-called social reform. Therefore, let us stop tinkering with our own institutions and avoid the importation of European political tragedies through duplication of European systems and procedures. God knows

we have gone far enough in relegating our rights to the whims of politicians, remarks the *Nebraska State Medical Journal*. Medical service rendered under the American plan has been a success in every way. The American House of Medicine can continue on its steady progress only through personal and professional freedom of thought and of action.

THEY COME, THEY GO

Another of the old drugs is ready for the discard. Several decades ago, creosote was highly recommended in the treatment of respiratory diseases, and it once was advocated in the management of tuberculosis. The Council on Pharmacy and Chemistry of the American Medical Association has made a protracted study of the matter and in a report published in the *Journal of the American Medical Association* for November 11, 1939, it is stated that creosote lacks value in these cases. Formerly it was claimed that creosote increased sputum production, but the Council is unable to substantiate this claim.

CONQUEST OF SYPHILIS

"The problem presented by the prevalence of syphilis may appall us, but let me point out that twenty-five years ago this was true also of diphtheria, which at that time caused about 1,400 deaths in a single year. This year, diphtheria deaths will probably not exceed twenty-five. With the means at our disposal we can make much greater advance in the future in the conquest of syphilis, and it is my hope that the time will not be too far distant when syphilis can be discussed as largely a problem of past history."—*John L. Rice, M.D., Commissioner of Health, New York City*

IMMOBILIZATION OF THE CHEST IN PLEURISY AND RIB FRACTURE

H J CHRISTENSEN, M D , Poughkeepsie, New York

A PHYSICIAN wishing to immobilize the chest must choose between adhesive strapping and an immobilization belt. This choice is nearly a hypothetical one because immobilization belts have not gained wide enough use to receive such consideration. Adhesive strapping is almost exclusively used. The obvious reasons are that adhesive is cheap, nearly always on hand, and it is the established practice.

It is the purpose of this paper to establish, in fact, this choice by describing immobilization belts which are as readily available and nearly as cheap as adhesive plaster itself. Two types of immobilization belts which any doctor can make of cotton, gauze bandage, adhesive, and tongue blades, are here described. They are Sam Browne type of belts having tongue blades as stays and hospital cotton as padding.

The objections to adhesive are skin irritation, slipping of the adhesive with loss of immobilization, the time limit when the skin will no longer bear up under the adhesive, inability to examine and treat the parts covered by the adhesive, and finally, the mounting discomfort of the patient until the adhesive is removed. The ordeal of removal is approached by some patients as a major operation.

There are certain requirements which the immobilization and the method of immobilization itself should satisfy. They may be listed as follows:

Immobilization

- (1) adequate
- (2) sustained
- (3) controlled
- (4) comfortable

Immobilizer

- (1) cause no skin irritation
- (2) adjustable
- (3) temporarily removable (to permit

examination and treatment of parts which it covers)

- (4) low cost
- (5) easily made
- (6) of readily available "office" or "emergency" materials
- (7) light weight
- (8) duration of application unlimited

Two types of belts embodying all the above features, made of cotton, gauze bandage, adhesive, and tongue blades (Fig 1) are here described.

Pleurisy

In pleurisy, warmth in addition to immobilization is desired. To satisfy both these requirements the belt is made as follows:

The "core" or stay portion (Fig 2) is made by placing tongue blades side by side, about three-eighths of an inch apart, on a piece of adhesive which is long enough to encircle the chest outside the cotton padding. This "core" is then placed in the middle of a single piece of hospital cotton of one or two layers according to thickness, and of adequate length to encircle the lower chest, and the overlapping cotton edges (giving extra warmth) are folded over and secured by spiral turns of wide gauze bandage running the length of the belt (Fig 3). A wide strip of adhesive running the length of the belt secures the spiral turns of bandage on the outside.

A shoulder strap (Fig 5) is constructed of adhesive and cotton with a few stays of tongue blade cut to width and placed under the adhesive over the crest of the shoulder to prevent wrinkling.

The belt is now placed about the lower chest with the two ends meeting at the anterior axillary line on the side opposite the lesion. These ends are bridged and held together at the proper degree of immobilization with a wide piece of ad-

hesive of adequate length to hold securely. The shoulder strap is now placed over the shoulder on the same side as the lesion and attached to the outside of the belt by adhesive (Fig 6). Placing the shoulder strap over the shoulder of the side opposite the joined ends of the belt allows the belt to be slipped off over the arm. It would otherwise have to be slipped off over the head.

To remove the belt temporarily for examination or treatment (Fig 7) the adhesive joining the two ends of the belt is pulled back until the ends are released. The belt is then slipped off the arm. When the belt is replaced the same adhesive will serve again to hold the ends securely together. By proper adjustment of this piece of adhesive any degree of immobilization can be obtained.

As the cotton padding packs the belt loosens and adjustment is made, if necessary, by cutting off a tongue blade segment from one end allowing the belt to be drawn tighter. Patients can be instructed to keep the belt adjusted to give maximum comfort. If the cotton becomes soiled it may be replaced by fresh cotton over the old tongue blade "core." No adhesive should contact the skin.

Rib Fracture

In rib fracture, immobilization alone is desired. Warmth is not a necessary consideration. A cool, lightweight belt (Fig 4) is constructed by using only sufficient cotton padding to face the inner side of the belt, and attached by spiral turns of wide gauze bandage to the tongue blade "core." Thus the cotton does not overlap the edges of the "core" as described in the pleurisy belt. A wide piece of adhesive runs the length of the outside of the belt to secure the spiral turns of gauze bandage. The belt is applied in the manner described above.

In obese individuals with a high protruding abdomen no shoulder strap is necessary as the belt will not slip down. A very desirable feature is that belts of large size may be made up in advance and kept ready for use later to be cut down to

FIG 1 Materials

FIG 2 Construction of "core." Tongue blade stays on adhesive which overlaps to bind ends of tongue blades

FIG 3 Construction of "pleurisy" belt (outer side) showing overlapping cotton edges and wide adhesive securing spiral turns of gauze bandage.

FIG 4 Construction of "rib fracture" belt (inner side) showing cotton padding facing the inside of the belt only, and secured by spiral turns of gauze bandage

FIG 5 Construction of shoulder strap (inner side) with cotton turned back to show stay construction over crest of shoulder

FIG 6 "Pleurisy" belt applied

suitable size by simply cutting off a sufficient number of tongue blade segments with bandage scissors. A single piece of hospital gauze cut to size to cover the cotton may be used instead of the spiral turns of gauze bandage. Gauze bandage is illustrated because it is almost always on hand. A single piece of cotton outing flannel used as above to cover the cotton makes a still better belt. The waterproof type of adhesive is best suited for the belt.

Theoretically it is considered unwise to immobilize the "good" side of the chest along with the "bad" side. It is reasoned that the good side should be free to compensate for the restriction of the opposite side. Adhesive strapping properly applied, must extend well onto the good side, and in doing so also causes some restriction

FIG 7 Showing method of removing and reapplying belt after treatment

of the good side. In actual practice no bad effects on the good side have been noted. Furthermore, the circular type of belt has survived the test of several years' use. To my knowledge, the circular type of belt made of canvas or webbing reinforced with corset steels has been available at supply houses for several years.

The Sam Browne type of belt made of canvas or webbing reinforced with corset steels has been used for chest immobilization. These never gained wide use because of expense and cleaning difficulties. Dr. Richey L. Waugh,¹ New Orleans, used plaster-of-paris fixation bandages applied Sam Browne fashion to the chest. This is an excellent device, but the fuss and muss of applying plaster of paris has deterred its use. Furthermore, the belt cannot be made up in advance and kept on hand ready for use as those here described.

Patient (nervously) "I suppose the operation will be dangerous, doctor?"

Doctor "Nonsense! You couldn't have a dangerous operation for forty dollars"—*Medical Record*

"Does your husband still complain of thirst?" asked the doctor.

"He did at first," replied Mrs. Jenkins, "but I gave him a glass of water every time and he soon stopped."—*Medical World*

OBSTETRICS IN A GENERAL HOSPITAL

Ten Thousand Cases at the Bronx Hospital

J IRVING KUSHNER, M D , New York City,

(From the Obstetrical Service of the Bronx Hospital)

PRACTICALLY all of the published statistics dealing with maternal and fetal mortality are from strictly lying-in hospitals, or from hospitals where the "maternity staff" is composed entirely of men who have specialized in obstetrics. In former publications^{1,2} we have reported the statistics from a general hospital where many of the confinements are attended by doctors in general practice, with an operative incidence of 23.9 per cent, a maternal mortality of 0.3 per cent, and a corrected infant mortality of 3.1 per cent.

It has been said that "home delivery, even under the poorest conditions is safer than hospital delivery," also that "delivery by a midwife is safer than by a doctor," and again, "the general hospital is a veritable cesspool of puerperal infection."³ This report is made with the purpose of showing that in a well-regulated general hospital where the family doctor is permitted to confine his patients within certain definite restrictions it is possible to obtain results which compare favorably with those obtained in strictly maternity hospitals. This study is based on the experience at the Bronx Hospital from the time it entered its new quarters in July, 1932, through March, 1938. During this period there were admitted 10,000 women in labor, 3,166 on the ward service and 6,834 on the private services. These were in the proportion of 1 to 2.15.

On the ward service the expectant mother is required to register with the antepartum clinic before the seventh month of gestation. She is seen at intervals of two weeks and in the last month of gravidity every week to the time of delivery. The antepartum care consists of

a complete physical examination including blood pressure and urine examination, mensuration, hygienic, and dietetic regulation. The appearance of signs of toxemia, blood dyscrasia, or any complication indicates more frequent observation in the regular clinic, or a special clinic, or when necessary, hospitalization. During labor unnecessary examination and interference is eliminated, rectal examination instead of vaginal being used, and the work of the staff is carefully supervised. The private services observe a reasonable degree of proper prenatal care, and no operative procedure other than the low forceps operation can be done except under supervision. The low forceps operation is permitted only to alumni on the staff or to the men who have already shown their ability to perform this operation. All forceps operations are reviewed in the monthly obstetric conferences and also at a meeting of a committee of the medical board consisting of the attending gynecologist and obstetricians. There the indications and the results are discussed with the physician usually being present. No other operative procedure can be done except by the obstetric staff and the attending gynecologists. To three other men, permission has been specifically granted by the medical board because of their known ability.

All cesarean cases are reviewed by the committee referred to above and the surgeon's presence at this time is required. There is frank discussion of the indications and procedures employed irrespective of the result. This operation is limited to the attending gynecologists and obstetricians without previous con-

Read by invitation at the meeting of the Section of Obstetrics and Gynecology, the New York Academy of Medicine, December 27, 1938.

Totals		2350	18		138	
Frequency for operative cases			0 88 per cent		1 38 per cent	6 1 per cent

sultations All others are required to have approval by one of these before the laparotomy can be performed.

Provision has been made for the application by a surgeon for permission to do an elective cesarean He is required to submit a letter setting forth his reasons and this is considered at a meeting of the committee As a result of this committee's work the operative incidence as well as the number of cesarean operations has decreased

Operation Incidence—Of the 10,000 labors operative delivery was performed 2,350 times, a frequency of 23 5 per cent, with an infant mortality of 6 1 per cent (138 in 2,350) for the operative cases, as compared with 1 38 per cent for the total series In the operative cases a maternal mortality of 0 88 per cent was noted as compared with a general maternal mortality of 0 23 per cent It is of interest to note that of the 3,166 labors on the ward service, operative delivery was performed 507 times, a frequency of 16 01 per cent with an infant mortality of 1 09 per cent for the total cases and 6 7 per cent for the operative cases and with only 3 maternal deaths (Table 1)

Forceps Operation—On the private services the low forceps operation was done in the greater proportion of the cases as a prophylactic measure. The low forceps operation on the ward service, however, was strictly limited to definite indications in the interest of mother or child, i e., either maternal exhaustion from prolonged labor, or fetal distress as indicated by the character of the heart rate in addition to the mere appearance of meconium

There were 21 infant deaths in all the low forceps deliveries, as follows 5 congenital anomalies, 5 neonatal deaths due to cerebral hemorrhage, and 11 deaths from unknown causes (all these deaths were autopsied)

The 525 mid forceps operations in the entire series are divided into two groups (a) head anterior at the time of operation, 210, and (b) head posterior or transverse arrest position, 315

The indications were strict and ran parallel to those for low forceps on the ward service

The 21 infant deaths in the mid forceps deliveries include 10 cases where fetal heart was lost during labor, 3 babies that died of bronchopneumonia within the lying-in period, and 8 deaths due to cerebral hemorrhage (all these were autopsied)

The high forceps operation was done 25 times (4 times more frequently on private than on ward services) In all cases the operation was done for fetal distress on unengaged heads where versions were contraindicated The 5 fetal deaths all showed cerebral hemorrhage.

In this group of forceps operations there were 5 maternal deaths The details are appended (1) A primigravida who had a mid forceps for fetal distress after four and one-half hours of full dilatation, occiput anterior She sustained a left cervical laceration which was repaired The cervix and vagina were packed and 1,000 cc. of glucose infusion was given After some time, bleeding recurred and she died five and one-half hours after delivery after a further attempt to repair the cervix (2) A primigravida, who had a mid forceps operation for ineffectual pains The patient developed circulatory collapse and anuria and died in uremia four days later (3) A primigravida, admitted with a left lower lobar pneumonia and in labor with full dilatation and head on the perineum A low Elliott forceps on a premature 4 lb 8 oz baby was done. The baby is living The mother expired the third day, postpartum, in circulatory failure (4) A primigravida twin pregnancy, was admitted for vaginal bleeding She was bagged but the cervix dilated very slowly (four days) Meanwhile the patient developed a temperature. At the end of four days, because of fetal distress, a mid Kielland forceps was done on the first baby for fetal distress, the second baby, by version and extraction The placenta was removed manually The patient developed sepsis and expired. Necropsy-septic endometritis and suppurative phlebitis right uterine and internal iliac veins The babies are living (5) A primigravida, had a mid forceps operation for fetal distress—O A position Elliott for-

ceps failed to move the head, and Kielland forceps were substituted—8 lbs 10 oz stillbirth was delivered. The patient developed circulatory failure and expired the third day postpartum.

Analysis of these deaths shows 1 due to pneumonia, 1 due to sepsis, 1 due to hemorrhage, and 2 due to circulatory failure, probably sepsis.

High				5	
Totals	5	3	10	18	11
			47		

Versions—Internal podalic version and extraction was employed 73 times, an incidence of 1 in 137 or 0.7 per cent with the indications shown in Table 3.

Here the fetal deaths included 6 premature babies (less than 3 lbs in weight), 12 full term intrapartum stillbirths (8 after failure of forceps), 1 macerated fetus, 3 congenital anomalies in compatible with life, and 3 full term neonatal deaths from cerebral hemorrhage.

There was 1 maternal death—a primigravida, admitted in eclamptic convulsions which could not be controlled despite Strogannoff therapy. After full dilatation, Kielland forceps failed and version and extraction was done on dead baby. Mother expired in coma one day postpartum.

Breech Presentation—Breech presentation was encountered 357 times, an incidence of 3.5 per cent.

The treatment was, where possible, strictly conservative, allowing labor to proceed until the buttocks had passed through the vulvar orifice, from which point manual help from the operator completed the delivery. This constituted what we called a spontaneous breech delivery. Any other procedure was termed a breech extraction. The latter was done 107 times (Table 1). In the spontaneous group there were 4 infant deaths among 250 cases, a percentage of 1.6 per cent. Two were macerated fetuses, 1 was a congenital anomaly, and 1 was premature (second of twins). In the extraction group there were 29 fetal deaths, a percentage of 25.2 per cent. Three were anomalies, 1 was a premature, 1 was a

neonatal death from partial atelectasis, and 24 were deaths in all probability due to the extraction (Table 4). The mortality for the breech extraction as a whole was thus 33 in 357 or 9.2 per cent (Table 4).

Cesarean Section—Cesarean section was resorted to 279 times, a frequency of 2.79 per cent or an incidence of 1 in 36. The indications are shown in Table 5. These 228 patients were operated upon only after a test of labor, the other patients including 20 in the previous section group, 19 in the "ablatio" group, 7 in the cardiac group, 4 in the elective toxemia group, and 1 in the abdominal pregnancy group, were operated upon without such labor. In all, the presenting part was unengaged at the time of operation.

The types of operation are also noted in the table, the classical operation being done 149 times, the two flap, 107 times, the Latzko, 14 times, and the Porro, 9 times (Table 5).

The Porro operation was done 5 times for placental apoplexy, 2 times for intrapartum infection, and the other 2 times for failure of the uterus to contract following classical sections both complicated by intramural fibroids.

The Latzko procedure was done for potentially infected cases, with 1 fetal death and no maternal deaths. This has been reported elsewhere (Table 5).

The details of the maternal deaths with the cesarean operation (11 in 270), a percentage of 3.9 are added.

1 Primipara at term, central placenta praevia, generally contracted pelvis. Classical section. Died on sixth postoperative day of sudden cardiac collapse. Stillbirth. Peritonitis?

2 Primipara at term, central placenta praevia. Classical section. Died on tenth postoperative day of peritonitis. Living baby.

3 Primipara at term, funnel pelvis, frank breech. Classical section. Died on sixth postoperative day from paralytic ileus. Living baby. Peritonitis?

4 Primipara at term, contracted pelvis, nonengagement at end of twenty-four hours with membranes ruptured eight hours. Two flap section. Neonatal death. Streptococcus hemolyticus septicemia.

5 Primipara at term, flat rachitic pelvis. Intrapartum sepsis. Porro section. Autopsy. Localized peritonitis. Living baby.

6 Primipara at term, flat pelvis, two flap section for nonengagement at end of thirty-six hours of ruptured membranes and eight hours of labor. Died of pneumonia. Living baby.

7 Primipara at term. Pre-eclamptic or chronic nephritic. Elective classical section.

Expired five hours postoperative of shock. Living baby

8 Forty-two-year-old primipara Cervical malformation. Classical section after several hours of ruptured membranes Abdominal distention not relieved by exploratory laparotomy No evidence of peritonitis at operation. Expired six days postoperative. Living baby

9 Primipara. Placenta praevia Classical section after two days of ruptured membranes (fetal heart lost on admission) Expired on sixth day with signs and symptoms of peritonitis Dead baby

10 Primipara Rheumatic heart disease. Class III Classical section immediately upon rupture of membranes with passage of meconium Expired four days postoperative of cardiac failure. Living baby

11 Primipara. Rheumatic heart disease Class II B Classical section after 6 hours trial of labor Expired on table. Living baby Cardiac failure, acute.

To summarize, there were 2 cardiac deaths, 6 deaths due to peritonitis, 1 due to sepsis, 1 due to pneumonia, and 1 from postoperative shock

The 28 fetal deaths occurred 16 times in cases of "Ablatio" (fetus already dead when section was done), 8 in cases of placenta praevia where fetal heart was lost before operation, 1 in a mother who died of streptococcus hemolyticus

sepsis, 1 a high forceps had been attempted at home before admission to the hospital, and later a Latzko section done in the interest of the mother, one neonatal death from unknown causes, and one neonatal death in the abdominal pregnancy

Maternal Mortality

In this series of 10,000 cases there were 23 maternal deaths, a frequency of 0.2 per cent, already described under the different headings and itemized in Table 6 and summarized by causes in Table 7

Infant Mortality

In this series there were 423 infant deaths, a mortality rate of 4.23 per cent, 97 were macerated fetuses and 34 were congenital anomalies incompatible with life, leaving a corrected mortality of 2.92 per cent. Of these, 132 were premature infants (i.e., less than 3 pounds) leaving a full-term corrected infant mortality of 1.6 per cent.

Comment

We have presented an analysis of a series of 10,000 cases in a properly

LATE IRRADIATION REACTION IN BLADDER WALL FOLLOWING THE USE OF RADIUM IN UTERINE DISEASE

CHARLES C HERGER, M.D , and ALPHONSE A THIBAudeau, M B , Buffalo, New York

(From the State Institute for the Study of Malignant Disease, Buffalo)

EXTENSION of uterine cancer into the genitourinary tract has been well recognized for many years. In advanced malignancy, obstruction of the urethra, invasion of the bladder wall—with or without fistula—and occlusion of the ureters, with primary kidney atrophy, hydronephrosis, or pyelonephrosis has been foreseen. But with the advent of irradiation therapy we must consider not only the complications of the natural progress of the disease but also the immediate and late effects of the treatment itself, which materially add to the difficulties of the management of this group of patients. It is of great help in planning the treatment of these patients to make a careful urologic examination before any radiation treatment is initiated. We may thus not only recognize those individuals in whom surgical treatment is of prime importance, but we will also know the status of the urinary tract before treatment is begun so that adverse developments may be interpreted in the light of the initial pathology. This paper does not concern itself with the immediate effects of irradiation treatment on the bladder mucosa, but rather with the later manifestations in those women presumably cured of uterine disease who have bladder lesions which we recognize as a result of the therapy employed. While only a small proportion of patients treated develop these late sequelae, it is desirable that their nature and importance be recognized. Determination of their cause may prevent their occurrence in future patients.

There are two phases of late radium reaction in the bladder wall—the ulcerative and the telangiectatic. In the first phase, occurring in from three months

to ten or more years after treatment, the patient, after a period of apparent good health, more or less suddenly complains of frequent and painful micturition usually accompanied by slight hematuria. Cystoscopic examination reveals, in a typical case, an area of ulceration and necrosis, surrounded by bullous edema and scattered areas of telangiectasis. A uniform finding in such cases is that the lesion appears in the midline, or just to one side of it, and just above the interureteric ligament. This phase under appropriate treatment, and if the ulceration is not too deep, heals in a few months. In an occasional case, however, the ulceration persists for a much longer period. In the telangiectatic phase the main symptom is hematuria. The bladder mucosa is studded with small telangiectatic areas in which capillary blood vessel tufts are seen, elevated above the surrounding mucosa. This phase accompanies the ulcerative stage and usually persists long after the ulceration has healed. Bleeding from these cases occasionally assumes alarming proportions, necessitating transfusion. Usually, however, the hemorrhage can be controlled by transurethral coagulation. The telangiectatic phase is undoubtedly the much milder but the more persistent form of reaction, while in turn the ulcerative phase may itself be mild and produce few symptoms.

In the majority of patients it is relatively simple to determine whether we are dealing with an extension of the malignant process into the bladder mucosa, or a late radium reaction. The diagnosis can, in most cases, be made from the cystoscopic picture. In tumor invasion the posterior wall of the bladder is first elevated (the

sion A more extensive invasion of the submucosal and muscle layers is sometimes seen and in these cases it is often difficult to distinguish between the histologic picture of late radium reaction and that of infiltrating carcinoma of the bladder. The cells in the former show a change in cellularity and in some cases frequent mitotic figures are seen. While this overgrowth of squamous epithelial cells somewhat resembles that seen at the edges of a skin ulcer, in many cases it is much more irregular in its growth and more penetrating in its infiltration—a condition possibly due to the more areolar nature of the underlying stroma in the bladder wall. So extensive and irregular was this infiltration of submucosa and muscle in 2 of the biopsies sent to the laboratory without adequate history, that a histologic diagnosis of carcinoma was primarily made, to be subsequently altered when a more complete review of the clinical history was made. Both of these patients have recovered without further radiation and on the usual treatment. In these 45 patients, in whom late radium reactions in bladder mucosa were observed, the age incidence was identical with that of the age incidence of malignancy in the cervix, and as most of our cases suffered from this primary condition this observation is not significant. An analysis of the length of time elapsing from the application of radium to the onset of bladder symptoms showed a wide variation of from three months to eleven years. In 65 per cent of the patients, however, these symptoms appeared in from nine to twenty-four months. It was noted also that the primary dosage of radiation applied was in 36 per cent of these patients below 3,500 mg hours in the pelvis. This is the maximum dosage which Dean considers safe from the standpoint of bladder damage. The remaining 64 per cent of this group of patients received more than 3,500 mg hours radiation in the pelvis. This was almost universally applied in the form of tandem tubes of 100 mg each in the uterus for a total of 2,400 mg hours supplemented by gold seeds of radium emanation

in the cervix for an additional dosage of 1,000 to 2,000 millicurie hours, making a total of 3,400 to 4,400 mg and millicurie hours.

Treatment

If careful pelvic and cystoscopic examination fail to make the diagnosis certain, it is safer to use a trial period of treatment for radium reaction. In the ulcerative phase, effort must be directed to control infection and to prevent the development of calcareous deposit in the ulcerated area. Instillation of argyrol or similar antiseptic solutions once or twice weekly, with the administration of the newer urinary antiseptics, sulfanilamide or mandelic acid, may be used. Calcium mandelate is well suited to this type of lesion, as it helps to maintain the acidity of the urine and it is also bactericidal. Urotropin should be avoided as it is apt to further irritate the ulcerated bladder. With the treatment, relief of symptoms is usually fairly prompt, though the ulceration may persist for several months. Occasionally the lesions respond poorly to the above treatment and, due to the action of urea splitting organisms, the bladder becomes the seat of an alkaline cystitis and the ulcers the site of alkaline incrustations, which may have to be removed with the rongeur forceps. After the ulcerations have healed, the bladder mucosa often shows telangiectasis in the healed area with occasionally hematuria which may be profuse.

The question of individual idiosyncrasy in the causation of these bladder lesions has received considerable attention. The fact that a very small proportion—a fraction of 1 per cent—of patients who have had radium treatment in the pelvis, show late bladder reactions would perhaps lend some point to this explanation. We have seen late radium reaction in the bladders of patients treated with minimal doses of from 800 to 1,000 mg hours for uterine fibroid. However, other factors must be considered. Among these, the improper placing of tubes or seeds, or accidents such as the slipping of radium bear-

bombardment of French observers) The mucosa over this area is at first unchanged but later becomes injected and edematous and finally is thrown up into ridges and folds, until, with the eruption of the tumor cells through the mucosa, typical nodular masses of tumor tissue can be seen. In contrast to this cystoscopic picture, in late radium reaction we find one or more sharply circumscribed areas of slough and ulceration. Immediately surrounding these areas is found a zone of bullous edema while interspersed between or around the ulcerations typical blood vessel changes are noted, with varying degrees of telangiectasis, from simple dilated vessels to definite elevated areas showing thickened mucosa underlaid by masses of dilated vessels. These changes are confined to a definite location in the bladder wall, i.e., just above the interureteric ligament and in the midline or very close to it. Symptomatology is also significant. Invasion of the bladder wall by tumor gives symptoms of insidious onset, slowly increasing in severity, with first a frequency of urination, increasingly painful, with eventual hematuria. In the late radium reaction, on the other hand, bladder discomfort is abrupt in onset with markedly frequent and painful urination and mild hematuria, or with marked and persistent hematuria.

Induration at the base of the bladder calls for careful consideration. It is usually present in tumor invasion but may also be found if deep ulceration of the bladder wall occurs. Absence of induration is highly suggestive of late radium reaction. In these patients the cystoscopic picture should verify the diagnosis. Occasionally, however, patients are seen in whom the diagnosis is still in doubt and in these a biopsy should be made.

The importance of differential diagnosis, as between tumor extension and late radium reaction, is of paramount importance. In the former, further irradiation is indicated, whereas in the latter it is emphatically contraindicated, as further insult to already damaged tissues might be disastrous.

Histologic study of tissue from 40 patients in whom clinical symptoms of bladder irritation were reported at the Institute shows interesting pictures. Where the material received includes the deeper portions of the submucosa and parts of the muscular wall, it is noted that the larger vessels show those changes which have long been recognized as possible results of radiation. This condition in the bladder wall of patients who have been subjected to proximate radiation therapy has been definitely referred to by Dean and others. In these cases we may observe thickening of the intimal layer with, in many instances, complete occlusion of the vessel lumens. A generalized fibrosis is apparent in these areas with marked increase in connective tissue of adult type. The superficial lesion consists of a subacute inflammatory infiltration of the submucosa with plasma and round cells accompanied by a proliferation of connective tissue cells of fibroblastic and myxomatous type below the surface epithelium. In this area, in most cases, a large number of delicate new formed capillaries appear—an apparent attempt to furnish the needed blood which the larger and deeper vessels now fail to supply. Areas of degeneration and necrosis appear in the epithelial cells of the bladder mucosa with eventual desquamation of the epithelial layer and the appearance of an ulcer. In the ulcerated area granulation tissue is frequent and necrosis common. The necrosis may extend deeply into the bladder wall and dense infiltration with polynuclear leukocytes is often seen. We wish, however, to call particular attention to an unusual and often misleading proliferation of squamous epithelium frequently seen in specimens removed from the bladder mucosa of these patients. In many instances, even before the ulceration of the epithelial lining of the bladder, islands of squamous epithelium are noted in the submucous area close to the epithelial layer but apparently definitely separated from it. The cells in these islands are usually well stained in fixed preparations and show signs of cellular activity and cell divi-

fistulas have been deliberately made, with excellent ultimate results

The picture is entirely different where ulcer alone exists, as these unfortunates suffer for months and even years. They need all the mental support which can be given to keep up their morale and not become hopeless drug addicts. These ulcers frequently become encrusted with phosphates which add greatly to the patient's suffering when they separate and are voided. Bleeding and infection are not infrequently present. The former (bleeding) has been fatal in one instance observed.

The best treatment is prevention, as Dr Herger has suggested. However, when ulceration is present a study of the infecting organism with appropriate internal urinary antiseptics to prevent phosphates forming and to keep the urine as sterile as possible, is in order.

As in certain types of renal and ureteral lithia-

sis acid sodium phosphate ammonium chloride internally, and phosphoric acid solution locally should be avoided as the calcium and phosphorous elimination will be increased, which will only add to the difficulties already present. Locally, soothing antiseptics as neosilvol, argyrol, weak solutions of mercurochrome, and neutral acriflavin have been used with some success. Novocain 4 per cent locally, followed in five minutes by diothane $\frac{1}{2}$ per cent, may give the sufferer a few hours of sleep at night.

Sedatives must be used with caution, especially the opiates. It is well to confine oneself to codeine which may be augmented by acid acetylsalicylate or the barbiturates.

At best the situation is a trying one to both patient and doctor.

In conclusion, let me thank the officers of this Section and Drs Herger and Thibaudeau for inviting me to discuss this presentation.

ing tubes from the uterine cavity into the vagina, must be considered of prime importance, because by such errors of technic and accidents, the bladder mucosa may be subjected to an unwarranted dose of radiation. Again in cervix carcinoma where the bulk of the tumor lies in the posterior lip and in the posterior portion of the canal, intensive radiation treatment in this area is particularly apt to affect the base of the bladder. It would seem probable also that these reactions usually follow a single fairly large radiation dosage in the pelvis. Some observers, notably those of the French school, advocate smaller divided doses given at intervals, in the hope of avoiding this complication. It would seem evident, therefore, from a consideration of the facts at hand that in order to prevent the occurrence of this complication of radium treatment in the pelvis, the following suggestions should be of value:

1. Technical and anatomic errors should be avoided.

2. Radiation dosage in the treatment of pelvic lesions should be divided, with repetition at proper intervals.

3. Careful urologic examination should be made before radiation treatment is started.

Conclusions

1. A small proportion of female patients treated by radium in the pelvis develop bladder lesions which have been classified under the heading of late radium reaction.

2. We have reviewed 45 such cases treated in the State Institute.

3. Care should be taken to distinguish this condition from primary or metastatic malignancy in the bladder wall.

4. The histologic picture in biopsy specimens from the bladder in these cases can closely simulate primary or metastatic malignancy in the bladder wall.

5. In any patient who complains of bladder symptoms after having received radium treatment in the pelvis, regard-

less of the dosage or elapse of time since treatment, this condition should be kept in mind.

Discussion

Dr Frederick J. Parmenter, *Buffalo, New York*—Drs Herger and Thibau deau have again wisely called our attention to the importance of differential diagnosis of radium ulcer of the bladder from the granulomas or tumors which so commonly occur. It would indeed be disastrous if a radium ulcer received additional radiation because of this error in diagnosis.

Several ways of arriving at a correct diagnosis are available. First, a carefully taken history which would reveal whether radium or x-ray therapy had ever been employed. In Dean's series, the average time of onset after the radium or x-ray therapy was one and a half or two years. In Dr Herger's series, the shortest was three months and the longest thirteen years. Second, if x-ray therapy alone has been employed, discoloration of the skin of the abdomen, external genitalia, and thighs may be observed on examination. Later, telangiectasis is common. Third, on cystoscopic examination, as Dean has pointed out, the location of the lesion upon the lower wall of the bladder in the midline is very suggestive. Fourth, biopsy is very important and will, if carefully interpreted, usually lead to a correct solution of the problem. It is the failure to remember these facts that leads one astray.

As has been pointed out, the effects of radiation upon the bladder may be comparatively slight, or very intense leading to ulcer in some instances and to perforation and fistula in others. In the perforation group, quite often the tissues will heal in time so that plastic repair can be successfully carried out. Perhaps these fistulas may be a blessing in disguise, because in other intractable bladder conditions, vesicovaginal

CHART 2 Shows instances of cases where the temperature came down lytically. One of the graphs shows a drop in the leukocyte count from 30,000 to 10,800 and 6,000 with reductions of the polynuclear from 91 per cent to 66 per cent and 35 per cent (Case 41).

eight to seventy-two hours. In the second group (11 cases) the temperature came down to normal within four to eight days. The third group (13 cases) represents pneumonias where the temperature came down in two to three days but rose again on account of complications such as pleural effusion or new foci of infection (see Charts 1, 2, 3). Of the 81 cases, 19 died, 62 recovered (death rate 23.5 per cent).

EFFECT AND TOXIC EFFECT OF SULFAPYRIDINE IN OLD AGE PNEUMONIA*

PAUL KAUFMAN, M D, New York City

(From the Second Medical Division of Welfare Hospital)

A REVIEW of the literature¹ on sulfapyridine treatment of pneumonia reveals that most of the published cases have been children, young adults, or middle-aged patients. It seemed, therefore, of peculiar interest to try the drug in old age pneumonia, a disease which is generally known to have a very high fatality rate.

Old age pneumonia is not a disease per se, however, clinicopathologic studies of a great number of old age pneumonia cases within the past years gave evidence of certain characteristic features which differentiate it from pneumonia of the young. It is often a feverless, complicated, insidious, and long drawn-out disease. Circulatory disturbances are almost always present. The forms might be either primary lobar croupous pneumonias, or confluent ones by the merging of lobular patches, frequently, single patches of lobular, or rarer, true bronchial pneumonias are present. Atelectasia, pulmonary edema, and renal involvements are more common than in the young. These differences and the lower rate of absorption and excretion of sulfapyridine and the lower basal metabolism make the effect and toxic effect of sulfapyridine less predictable in the old than in the young.

In this series, since the end of 1938, all together 81 pneumonia cases (46 men and 35 women) received sulfapyridine treatment. In all cases the diagnosis of pneumonia was confirmed by x-ray. Typing was attempted in all, and blood cultures in a great majority of cases, but only a small percentage showed positive results.

Age Distribution—A majority of the patients belonged to the age decades

between 70-79 (34 cases) and 60-69 (27 cases). The rest of the cases were divided as follows: 7 between 80-89, 4 between 40-49, 7 between 50-59, and 2 were over 90 years old. We could not find any relationship between the effect of the sulfapyridine and the age decades since the number of cases in the different age groups was too small to permit any such conclusions.

Type Distribution—There were 8 type I, 3 type II, 13 type III, 3 type IV, 2 type VI, 5 type VIII, 1 type IX, 1 type XI, 1 type XII, 2 type XIV, and 1 type XVII. In 12 cases nontypable diplococci, and in 8 cases hemolytic or other long chained streptococci were found. There were 21 cases bacteriologically "relevant."

Summary of the Clinical Experiences

Dosage—Usually 2 Gm were given as an initial dose followed by 1 Gm every four hours until enough of the drug had been given to make 12-22 Gm. Some times smaller initial or larger total doses were considered more advisable. The blood level of the free and combined sulfapyridine was determined in several cases. Blood counts of all the cases were taken every few days. These, the temperature, and the general improvement of the patients were indicators as to whether enough of the drug had been administered.

Effect of the Drug—In the course of a study on the mouse protective value of capsular pneumococcic polysaccharides against pneumococci, the effect of the drug was studied alone and in combination with the polysaccharides. Thirty mice were divided in three groups and we found that the rate of survival was almost twice as high in the group which received polysaccharide plus the drug as in the

* This work is part of a study on old age pneumonia which was started at the Neurological Hospital in 1937 and continued at the Welfare Hospital.

Toxic Effects—We gave toxic doses of sulfapyridine to 15 mice, and vomiting, muscular twitching, tremor, and finally cessation of respiration were observed between May 3 and June 1, 1939, 142.6 Gm of sulfapyridine was given orally in a tragacanth emulsion (Table 1) to a rabbit of 5,900 Gm. Toxic effects observed were restlessness, tremor, and increase in temperature. On June 6, 1939, the rabbit was chloroformed. Autopsy²

TABLE 1—TOXICITY OF SULFAPYRIDINE IN RABBIT

Date	Amount Given (Orally) Gm.	Symptoms
May 3	1.0	None
May 4	2.5	None
May 8	2.5	None
May 10	2.5	None
May 11	5.0	Restlessness vomited once
May 22	10.4	Slight twitching restlessness
May 23	10.4	Vomiting and twitching
May 24	20.8	Vomiting, muscular twitching and tremor
May 25	37.5	Immediate tremors, chills, followed by fever
June 1	37.5	Vomiting slight rigidity
Total	142.6	
June 6	Animal chloroformed for autopsy	

TABLE 2—AMOUNT OF SULFAPYRIDINE IN THE DIFFERENT ORGANS OF RABBIT AFTER TOXIC DOSES

Organ	Weight of Specimen Used (Gm)	Total Mg per 100 Gm of Organ	Free	Combined
Brain	2.5796	3.7	3.7	0.0
Liver	1.7630	23.1	5.84	17.26
Lung	2.0353	17.4	6.1	11.3
Kidney	1.9845	194.0	100.0	94.0
Heart	1.4516	16.3	7.6	8.7

showed no gross pathologic changes except in the kidneys which were strikingly pale. Microscopic examinations, however, gave the following results:

Kidneys kidney architecture is well preserved. Changes found: (1) considerable congestion in the intertubular tissue, (2) occasional fluid exudation into the Bowman's space of the glomeruli. A slight degree of tubular cloudy swelling is present.

Liver large areas of liver degeneration and vacuolization (hydropic degeneration).

Spleen somewhat larger and softer, showed marked congestion.

Lungs no marked abnormalities.

Heart some pallor of muscle fibers is present. There is also a moderate degree of fragmentation. The vessels appear congested.

The different organs were examined⁴ as to their sulfapyridine content. The result is shown in Table 2. Most of the sulfapyridine was found in the kidneys (194.0 mg per 100 Gm of organ) in both the free and combined forms. The liver also showed a considerable amount (17.26 in combination and 5.84 in the free form).

The toxic effects in human beings can be summarized as follows:

1 Effects on the stomach which were mostly of central and only rarely of local origin were evidenced by nausea and vomiting, this occurred in about one-half of the cases. Its occurrence can be diminished if the drug is given on a full stomach or with small doses of barbiturates.

2 Effect on the kidney, resulting in calculus formation by the acetylated sulfapyridine crystals. Depression of kidney functions is fairly common. We noted them in 12 cases. Since the kidneys of old patients are often affected, we checked up the blood chemistry and urinary signs in almost every case and often found higher NPN and urea nitrogen values which usually came down to normal after recovery. In 2 cases hematuria was noticed with albuminuria and casts and without any change in the blood picture, in both cases an increase in the urea N value was present. Both of these hemorrhagic nephritises cleared up after termination of the treatment.

3 Effect on hemopoietic system. Accompanying graphs show many instances of abnormally high white cell counts and then radical reductions. This was only partly due to the different states of the disease and partly to the stimulative and toxic effect of the drug on the bone marrow. Case 41 in Group 2 is illustrative of this. We saw 3 cases where milder hemolytic anemia with hematuria and low erythrocyte and hemoglobin values was noted. Sometimes the hemolysis is not of such a degree as to cause hematuria and it is revealed only by increased urobilinogen in the urine and the feces. In a few cases cyanosis was noted following the drug treatment. It was partly due to the cardiac condition and partly to the pneumonia itself, but it was never as serious as in the sulfanilamide treated cases, oxygen usually helped. One of the cases who received 34 Gm of sulfapyridine showed an interesting feature in the behavior of the white and red cells. The wbc went from 8,900 to 10,800–10,000–11,800–19,600–54,900 and the differential showed increasing number of immature cells. From one to as many as

thirty-two normoblasts were present. Then megaloblasts began to appear. There was a great deal of polychromia and anisocytosis. This blood picture evidently was a result of abnormal irritation of both the leukopoietic and erythropoietic systems by the sulfapyridine. The patient died six days after admission with signs of cardiac failure. No postmortem was done.

4 Toxic effect on the nervous system manifested itself by increased mental restlessness and irritability followed by twitching and increased mechanical irritation of the muscles. In more pronounced cases muscular tremors were noted. The so-called drug fever which is due to irritation of the thermoregulating centers belong to this group. We noted these effects in 3 cases. After discontinuing the drug these symptoms subsided.

5 Skin rashes similar to the salicylate exanthemata were also reported. Its occurrence is rare, we saw it once in its milder form.

From the point of toxic effect one of the cases (Case 74) which came to autopsy is of interest. The patient improved after the use of sulfapyridine and had no temperature for two days. When the sulfapyridine was stopped the temperature rose again to 101 F and kept on rising although sulfapyridine was resumed. He received altogether 34 Gm and his blood level was 5.8, 7.6, 6.9 mg. The patient died with pulmonary edema, due to the cardiac condition. The autopsy showed resolving pneumonia and a fatty degeneration of the parenchymatous organs. How much of that was due to the pneumonia and how much to the toxic effect of the sulfapyridine could not be determined.

Sulfapyridine vs Serum Treatment—The vital question confronting the medical public is whether sulfapyridine will be able to replace serum therapy or whether the two should be used together. Our series cannot answer this question since serum was given only in a few cases. From hospitals where younger groups are treated, comparative studies were pub-

lished on this point. Nevertheless, if one considers the severe strain of serum therapy in an old individual it seems justified to say that in old age pneumonia sulfapyridine has a wider field of application than serum therapy.

Analysis of the Fatal Cases—As it was mentioned before, out of the 81 cases, 19 patients died and 62 recovered, which would make a case fatality rate of 23.5 per cent. These results seem to be unsatisfactory when compared with those obtained in younger age groups. But it has to be considered that almost all of these patients had some cardiovascular disease, that the previous death rate in this age group used to be 75 per cent, and furthermore, that there was no selection of the cases and patients who seemed to be bad risks from the start were also included.

It has to be pointed out that at least 3 of the cases had a very bad cardiac status on admission and 2 of them seemed to have a marked improvement in the lung condition after the use of sulfapyridine but a few days later they died of cardiac failure, postmortem examination showed that the pneumonia was resolving and that the cause of death was cardiac failure.

Discussion

All the authors agree on the beneficial effect of sulfapyridine in pneumonia, nevertheless, their opinions clash as to how this action is brought about. The different theories propounded are (1) that it acts bacteriostatically, (2) that it stimulates the specific and nonspecific body defenses, (3) that it is a germicide, (4) that it decapsulates the bacteria (this theory is generally discarded), and (5) that it acts through neutralization of some metabolic activity of bacteria through some enzyme.

There are indications that the polysaccharides liberated through the action of sulfapyridine play a role in the effect. That the polysaccharides are very potent antigens was proved by several investigators and also in our laboratory. They act as sensitizing agents and as such stimu-

late the antibody production. At the same time the initially liberated smaller amounts of polysaccharide protect from toxic effect of the large amounts liberated later. Postmortem findings have also shown that the drug has a stimulative (and in toxic doses deleterious) effect on the reticulo-endothelial system shown by changes especially in the bone marrow, liver, spleen, and lymph glands. This also may have a part in the beneficial as well as toxic effect when sulfapyridine is used therapeutically.

Summary

1 A report of the value of sulfapyridine in the treatment of old age pneumonia is given.

2 The reduction in the case fatality rate from an average of 75 per cent to 23.5 per cent is noted.

3 In this series not only the fatality rate was reduced but also the duration of the fever from an average of twelve days to an average of seventy-two hours.

4 Analysis of the fatal cases, of the toxic symptoms, and of the mode of action of sulfapyridine is given.

THE MANAGEMENT OF COMPLICATIONS ARISING DURING CYCLOPROPANE ANESTHESIA

HAROLD R. GRIFFITH, M.D., C.M., Montreal, Canada

(From the Department of Anesthesia, Homeopathic Hospital of Montreal)

CYCLOPROPANE first came into clinical use in 1933, and since then it has been administered many thousand times by hundreds of anesthetists and with varying degrees of satisfaction. I have been asked to speak about the management of complications arising during or after cyclopropane anesthesia. Before I attempt to deal with this subject I believe I should try, in the legal sense of the term, to "qualify" myself as an expert witness. So with no intention of boasting but merely as a statement of fact, I wish to record a series of somewhat more than five thousand personal administrations of cyclopropane since October, 1933, with no death on the table, and no postoperative death which could be related to the anesthetic. This complete absence of mortality is to some extent merely good luck, because patients will die suddenly sometimes whether under anesthesia or not, and regardless of who may be caring for them. During the past five years in the hospital with which I am connected there have been 5 anesthetic deaths, but it happens that in each case some anesthetic other than cyclopropane was in use—one was with chloroform, one with ether, one with avertin, one with intravenous evipal, and one under spinal novocain. Because of these accidents I do not condemn these agents, nor do I uphold cyclopropane merely because of an absence of mortality. I do feel, however, that our record refutes the argument that cyclopropane is too dangerous a drug for use as an anesthetic agent. We have not picked our best risk cases for cyclopropane but have found it so satisfactory for so many types of operations, that during the past year 97 per cent of all my own anesthetics have been with

cyclopropane. Our 5,000 cases include 2,256 abdominal operations, of which 340 were in the upper abdomen. There were 1,567 cases in which an endotracheal tube was used, 850 of these being tonsillectomies in both children and adults. There were 528 for obstetrical deliveries, of which 201 were cesarean sections. The patients have been of all ages from six days to ninety years, and included in the series are many patients with heart disease and acute or chronic respiratory infections. It is inevitable that in such a large number of cases complications should have arisen, and it is about some of these complications and their management that I wish to speak.

Respiratory Depression—A difficulty which I have experienced during cyclopropane anesthesia is a tendency in some patients to depression or temporary cessation of respiration. This is most frequently seen in patients who are somewhat resistant of the anesthetic and to whom the anesthetist is giving a high concentration of cyclopropane. The patient may suddenly become deeply anesthetized and stop breathing. The treatment here is obviously to give more oxygen, to give it quickly, and in an effective manner. It is usually necessary only to dilute the mixture in the breathing bag with oxygen and to use a little manual pressure on the bag to re-establish respiration, but in some cases on account of an obstructed airway this is ineffective, so an endotracheal tube should be introduced quickly in order to get oxygen into the lungs before the asphyxia becomes serious enough to affect the heart. I cannot speak too strongly of the life-saving value of endotracheal oxygen in all forms of respiratory depression during

*Read by invitation at the Annual Meeting of the Medical Society of the State of New York
Syracuse, April 27, 1939*

anesthesia, and I feel that it is a primary duty of everyone who calls himself an anesthetist to become expert in the introduction of endotracheal tubes. There is only one way to become efficient in this not too difficult technic, and that is to practice at every possible opportunity. In order to practice intubation one should have laryngoscope and tubes at hand at all times in the operating room, and frequently insert a tube during or after an operation. This can be done carefully without damage to the patient, and avoids the danger of a failure at a critical moment by one who has had no experience except during the excitement of a crisis. As to methods of intubation, my personal preference is for a semirigid French silk catheter introduced through the mouth with a Guedel or other type of direct laryngoscope. Magill's method of blind nasal intubation with soft rubber tube is useful for normal anesthesia, but it is not always effective as a resuscitative measure in an emergency, and the anesthetist who is not accustomed to using a laryngoscope is then at a great disadvantage. *The most important single piece of advice for anesthetists contemplating the use of cyclopropane is to practice endotracheal intubation.*

With cyclopropane as with other anesthetic agents the maintenance of a free airway is a fundamental necessity. When there is obstruction to breathing from a tongue that is hard to control, the rubber Guedel airway may be introduced, or better still the "pharyngeal bulb gasway" designed by Dr. Beverley Leech. I have used this simple device in hundreds of cases with great satisfaction, and it allows also the use of cyclopropane by closed circuit for teeth extractions and other operations where a mask would be in the way. Spasm of the larynx, with a resulting "crowing" type of obstructed breathing is occasionally observed, especially in patients who are resistant to anesthesia. This is not usually a serious sign, and may be relieved by diluting the patients' atmosphere with oxygen or helium. I have kept a cylinder of helium on our gas machines for several years, and

I am of the opinion that it has definite value in relieving certain types of obstructed breathing in patients under anesthesia. However, none of these measures takes the place of oxygen by endotracheal tube in real cases of respiratory obstruction or asphyxia.

Pulmonary Atelectasis—Burford¹ has described several fatal cases of massive collapse of the lungs during or immediately after cyclopropane anesthesia, and he has suggested that these and also commoner and milder cases of postoperative atelectasis may be due to the rich oxygen atmosphere and shallow respiration which are usually associated with cyclopropane anesthesia. This hypothesis is interesting but I cannot subscribe to it as the sole or even the principal cause of atelectasis for the simple reason that in all our 5,000 cases of cyclopropane anesthesia we have had no single case of serious collapse, and the incidence of the milder forms of partial atelectasis is less than it used to be following ether or ethylene or nitrous oxide and ether. I believe, however, that the introduction of air into the anesthetic atmosphere is a good practice, and I am impressed by the simple device of a sphygmomanometer bulb attached to the breathing bag for this purpose as described by Colby.²

I believe that the factors which prevent atelectasis are (a) open airways during and after anesthesia, (b) nonirritating anesthetic, and (c) adequate use of pharyngeal and tracheal suction after anesthesia.

If these factors are properly attended to one need not worry about the absorbability of the anesthetic atmosphere. Mild cases of atelectasis have occurred in our experience following cyclopropane but the symptoms have developed from one to six days after the anesthetic and could not possibly be due at that time to pockets of cyclopropane remaining in the patient's lungs. I have a theory, shared by Leech, of Regina (who has had a wide experience with cyclopropane) and probably also by others, that cyclopropane anesthesia is better without the addition of ether, vinethene, chloroform, or other

volatile agents In our experience the addition of ether causes increased secretion and obstructed air passages, and does not improve muscular relaxation The objection will be raised that one needs ether to secure relaxation for upper abdominal surgery Our answer is that in our hospitals (Regina General Hospital and Homeopathic Hospital of Montreal) for the past three years we have never added ether to any cyclopropane anesthetic in order to secure better relaxation, and we believe that cyclopropane alone will give as good relaxation in any patient as will ether We admit that it is difficult to secure good relaxation in a few patients, but if cyclopropane will not do it, neither will ether The cases of fatal pulmonary collapse which I have read about have all been cases in which some ether was added to the cyclopropane Is it not possible that ether irritation played some part in the bronchial obstruction which must have preceded the collapse?

The other measure which I believe to be of great importance in the prevention of atelectasis is the proper use of suction It is our practice to introduce a small fenestrated rubber catheter with suction into the mouth of every patient after anesthesia, and to pass this catheter down the trachea if there is any evidence of obstructing bronchial mucus This is not traumatic, can do no harm, and I am sure has been the means of saving us much postoperative trouble Suction in all our operating rooms is by water suction pumps such as are in common use in laboratories and which can be easily connected to the existing plumbing at very little expense I don't believe enough emphasis has been placed upon the value of suction in the armamentarium of the anesthetist

Acute Pulmonary Edema—I have reported elsewhere³ a case of acute edema of the lungs occurring in an apparently healthy adult patient during the course of cyclopropane anesthesia for a herniotomy The patient became cyanosed and it was found that the bronchi and trachea were filled with a large quantity of frothy

serosanguineous fluid An endotracheal tube was introduced at once and a large amount of this fluid removed by suction, then endotracheal oxygen was administered and the patient suffered no serious after-effects Dr Kenneth Heard, of Toronto, has told me that he recently had a similar case which he treated in the same manner, and with equal success

I wish to record in more detail another case of acute pulmonary edema. An apparently healthy young woman went through a long and difficult labor ending in forceps delivery She was given intermittent nitrous oxide and oxygen for one hour before delivery, then was anesthetized with cyclopropane for the actual delivery and repair, a period of about half an hour During the cyclopropane anesthesia there was some trouble with mucus and the patient vomited fluids, but the condition was not regarded as unusual, and she was sent back to her room conscious, with a good color and a normal pulse rate One hour later she suddenly developed dyspnea and became cyanosed Oxygen was administered by mask without relief I was called and found her semiconscious, with shallow rapid respiration, an extremely rapid feeble pulse and with many coarse rales throughout her chest We made a tentative diagnosis of acute pulmonary edema, although she was not at that time spitting up any mucus, and in spite of her extremely serious condition I anesthetized her again with cyclopropane in order to introduce into her trachea a soft rubber suction tube With this we withdrew several ounces of very tenacious mucus, and then kept up oxygen by the nasal catheter method An x-ray of the chest at this time confirmed the diagnosis of widespread pulmonary edema. I was afraid to use suction again down the trachea on account of the extremely weak condition of her heart, so we contented ourselves with sucking from her pharynx what mucus was being coughed up, and continuing the oxygen After three hours she showed some improvement, consciousness returned, and another x-ray showed that the edema was diminishing

Twelve hours later there was evidence of beginning consolidation in both bases, and soon she was again in extremis on account of bilateral bronchopneumonia. I attributed this complication to the very tenacious character of the mucus in her chest in contrast to the thin serous exudate we had seen in other cases of acute pulmonary edema. She was given sulapyridine together with continuous nasal oxygen for eight days. Her respirations continued for days at the unbelievably high rate of sixty to eighty to the minute, but she made a good recovery and was discharged from the hospital perfectly well sixteen days after delivery.

After these experiences I might have believed that there was something peculiar to cyclopropane which tended to induce acute pulmonary edema in a few individuals, if it had not been for an almost identical experience with an obstetrical patient five years ago, when nitrous oxide and ether were used and not cyclopropane. In that case the patient did not develop pneumonia but she went through just the same pulmonary crisis an hour after delivery with a sudden filling of her lungs with frothy mucus. That was in our very early days of the use of cyclopropane and I remember being so thankful at the time that I had not used the new anesthetic in this case, for I never would have been able to convince myself or anyone else that the complication was not due to the "damned new-fangled gas!" We don't yet know what produces these attacks of acute pulmonary edema, but we do feel very strongly that immediate suction plus adequate oxygen is the proper treatment.

Cardiac Irregularities—In the reports on cyclopropane anesthesia, from both the laboratory and clinical points of view, there has been frequent mention of cardiac irregularity. I noted this effect in the sixth patient to whom I administered cyclopropane, and I have observed it in numerous patients since, but I can truthfully say that I have never seen any permanent or harmful result from the arrhythmia. I do not understand the underlying mechanism of these irregulari-

ties and I do not believe anyone else does in spite of extensive experimental and electrocardiographic studies, but I am going to be rash enough to say that from the clinical point of view, cardiac irregularities occurring in the human heart under surgical cyclopropane anesthesia may be disregarded. It is true that Meek⁴ and others have pointed out to us the effect of cyclopropane on the automaticity of dogs' hearts, and have produced experimentally ventricular tachycardias which make the animals liable to the onset of ventricular fibrillation by the addition of adrenalin. Also, they have suggested that a similar condition might possibly be produced in the human heart. However, the clinical situation is simply this—hundreds of careful anesthetists have administered cyclopropane to many thousand patients and no one has recorded any permanently damaging effect on the heart. Patients will die of heart disease at times under cyclopropane anesthesia, just as they die in their beds or on the street, but my own feeling is that cyclopropane is the safest anesthetic agent we have at present for patients with heart disease who require major surgical operations. In view of this clinical evidence, to say that we should not use cyclopropane because it is too dangerous for the heart is, in my opinion, perfect nonsense.

Postanesthetic Encephalopathy—Gebauer and Coleman⁵ have reported a case of so-called "post anesthetic encephalopathy" following cyclopropane, where at autopsy the brain showed evidence of severe degenerative changes. They believe that this condition might result from a localized cerebral anoxemia without any clinical evidence of cyanosis during the anesthesia. There are so many variable factors in different patients, that we must admit that anything is possible, but at least we may comfort ourselves that such a complication is extremely rare. I have had no such case in my experience.

Postoperative Shock—When we are confronted with circulatory shock following a major operation it is often hard to

decide how much of it is due to the surgery and how much to the anesthetic—it depends, perhaps, on whether one is a surgeon or an anesthetist. In any case, patients who have had cyclopropane anesthesia for any extensive abdominal operation or for some other type of operation in which there has been severe blood loss, do sometimes show evidence of more or less serious shock, and the anesthetist may be called upon to assist in supportive treatment. I have found that coramme in doses of at least 5 cc hypodermatically is a useful stimulant and that oxygen is of value, but that our principal dependence should be upon intravenous injections of glucose saline, or early blood transfusions. The relative infrequency of serious shock, vomiting, or abdominal distention after cyclopropane anesthesia is indicated by a study recently made of 300 of our cases of cesarean section. In the 200 cyclopropane cases there was nausea and vomiting in only 5 per cent, and severe distention in only 2 per cent.

With reference to the use of cyclopropane in obstetrics, I have been told that some obstetricians and pediatricians have suggested a possible harmful effect on the baby. When we published our original report⁶ on cyclopropane for cesarean section it never occurred to us to give statistics on this aspect of the subject, as we had never seen any such harmful effect. However, I have examined the records of our last 100 cases, and find that 5 babies did not live, of these, 4 were either too premature to be viable or were monstrosities. The other baby died when six days old, of peritonitis and pyloric stenosis. It was a small premature baby whose mother had been toxic. The other babies all left the hospital in healthy condition, so I do not see how anyone can logically consider cyclopropane as a factor in infant mortality.

Increased Bleeding During Operation—I suppose one should include in a paper such as this the controversial subject of the amount of bleeding during cyclopropane anesthesia. I have seen no convincing reports on this subject from laboratory or experimental workers, since

it is a very difficult question to prove experimentally. I can definitely say, however, from the clinical standpoint, that fear of excessive bleeding need not enter into our estimation of the value of cyclopropane. There is, perhaps, in some patients a slightly increased capillary flow from the superficial tissues while they are being handled, but in my experience this has never led to serious hemorrhage either during or after the operation. The surgeons who use cyclopropane most frequently and like it best, do not complain about bleeding, whereas we sometimes hear remarks about it from new men. Some patients do bleed more readily than others, but these "bleeders" lose as much blood when they are switched to ether as they do with cyclopropane.

Conclusions

To administer cyclopropane properly, and to avoid and to treat these complications which I have mentioned, the anesthetist must be reasonably intelligent, properly trained, and above all, a qualified physician with the fundamental background of the basic medical sciences which only a physician can possess. I have heard some hospital administrators and some surgeons argue against the use of cyclopropane on the grounds that it is safe only in the hands of experts. Surely it is no valid argument against a useful new anesthetic agent to say that the anesthetists of one's hospital are not qualified to administer a drug which is being used safely in many other hospitals.

The whole subject of the relationship between surgeon, anesthetist, hospital, and patient, and their relative responsibility, has recently been ably reviewed by a learned French Canadian judge in the Superior Court of the Province of Quebec.⁷ A few extracts from his remarks while rendering judgment are pertinent to this question. He says in part "The following propositions are established, (a) that the administration of a general anesthetic is a dangerous thing even to the point of possibly causing the death of the person submitted to it,

(b) that during the anesthetic surprises, complications, sudden and unforeseen situations, dangerous to the patient and capable of causing his death, may arise, (c) that with the presence of a physician specializing in anesthesia, and experienced in this branch of medicine, the life of the patient might almost always be saved when a complication arises during the anesthetic

The administration of a general anesthetic is at the same time a science and an art, easy, this science and this art, when all goes well, that is to say when no complication or difficulty arises in the patient, difficult and exacting of skill and experience, when a sudden and dangerous complication arises (these complications vary with the patient and never present exactly the same aspect) being able to cause death very rapidly, if a competent anesthetist, experienced and knowing how to act quickly in this particular complication, is not ready to cope with it with the discretion, the precision, and the ability which can come only from the union of medical science with experience, during the operation the life of the patient rests in the hands of the anesthetist quite as much as in those of the surgeon himself, and any complication resulting from the anesthetic puts the life of the patient in the balance

It follows that one cannot be too careful in the choice of this man

An anesthetic agent is a drug, which shows its action by certain signs and produces definite effects, by these symptoms and these signs one knows what is happening to the patient, and to understand these signs and to judge what may arise, it is necessary to know medicine

A nurse has not the required medical preparation to be able to cope with an accident during anesthesia, the reflexes, the pulse, the breathing, the color of the patient, these are the signs which would speak in a certain way to a specialist in anesthesia, and which by keeping him constantly informed of the condition of the patient, permit him not only to pro-

tect the patient by intervening at a critical moment, but also to foresee and prevent such a critical moment, that which constitutes the value of a medical anesthetist having a knowledge of physiology, is his ability to perceive quickly a sudden complication which may arise, to act quickly, to do what should be done and nothing else

The claim of the defendants that, during the operation to guard against and to cope with anesthetic complications the patient has at the same time the anesthetist and the surgeon is not admissible, the surgeon cannot and should not supervise the anesthesia, that is not his business, all his attention and his faculties should be concentrated on the operation itself, which he should execute diligently, carefully, and without the preoccupation of accessory or extraneous things, the anesthetist is, therefore, the only person who watches actually and completely the patient, he being ready to deal with complications which may arise with the anesthetic, when a critical situation does arise the surgeon, who should then suspend the operation, comes to assist the anesthetist, but it is still the latter who remains always the person in charge of the security of the patient "

In conclusion I would like to say simply that I believe cyclopropane to be the best and most widely applicable general anesthetic agent which we have available at the present time, and that the complications and dangers attendant upon its use should not frighten any experienced medical anesthetist

Case Reports

HYPERSENSITIVITY TO RABIES VACCINE

WILFRED DORFMAN, M.D., Brooklyn, New York

REPORTS on complications due to the administration of rabies vaccine (Semple)* are infrequent and usually limited to discussions of paralyzes. Many types have been noted,^{1,2} viz., a Landry's type of ascending paralysis, a subacute form corresponding to a myelitis type, a mild neuritic form especially striking the facial muscles, sphincteric disorders, and polyneuritic manifestations. These paralyzes have been considered by some authorities as cases of modified rabies, others have tried in vain to find the lesions of rabies on autopsy and have likewise been unsuccessful in trying to reproduce the lesion by injection of the brain substance into another animal.⁶ Stuart and Krikorian thought that these paralytic accidents were specific anaphylactic responses to the cord or brain substance used in the vaccine and felt that further refinement of the material would remove the dangerous elements.⁴ They describe 1 case in which the anaphylactic character of the reaction is evident.

A 5-year-old Palestinian Jewish girl, who was previously exposed to rabies and had received ten injections without ill effect, was scratched by a cat. Antirabic treatment was given for 10 days, the following day she did not feel well and two days later she showed some weakness in her legs. On the third day following the cessation of treatment, urticaria was present near the sites of injection, vomiting occurred, and the patient was unable to stand erect. Examination was entirely negative, except for the urticaria. On the fifth day the urticaria became more severe, as did the ataxia. On the seventh day the symptoms began to wear off gradually and one month later she was entirely symptom free.⁴

Rosenau described a flaring-up of the sites of injection during the course of treatment and felt that they represented a phase of hypersensitivity. The same author feels that the paralytic manifestations may be due to a form of anaphylaxis rather than to an untoward complication of treatment.⁶

The following observation is presented as a case of undoubted sensitivity to the vaccine.

In 1931, W. D. was a medical student. His past history was entirely negative except for a proved sensitivity to rabbit dander. This sensitivity had been demonstrated by his inability to do any laboratory work with rabbits, for in a short time marked ocular and nasal symptoms

would occur. His family history was negative, except for the presence of hay fever in his sister. He was exposed to a rabid dog in his home. There was no actual bite, but realizing the possibilities of infection through hangnails and cracks in the skin⁷ (since he had examined the dog during its illness), he thought it wise to take the prophylactic injections. Knowledge of his sensitivity to rabbit dander, and the realization that the Semple vaccine was made from the spinal cord of a similar animal, made him hesitant as to the advisability of taking the treatment. His theoretical ramblings, however, were stilled by the "sober" judgment of others. A skin test was done with 2 minims of the vaccine, the injection being made intracutaneously in the abdominal wall. A markedly positive wheal did not deter the overzealous vaccinator, and 2 cc of the vaccine was injected subcutaneously into the abdominal wall. Twenty minutes later at home, the student noted the onset of dizziness and a feeling that "all was not well." Exposure of the site of injection revealed a rapidly increasing red wheal with marked pseudopodial reaction and radiating redness to the axilla. Within ten minutes there was syncope, from which the patient was easily aroused, but it soon recurred. There was marked pallor, a generalized urticaria and slight but definite difficulty in swallowing. A physician was hastily summoned, but the patient recovered before his arrival. Adrenalin was administered and the subsequent course was uneventful.

It is of interest to note that during the student's undergraduate days (when one's idea of humor can reach limitless bounds), he had carried a rabbit's foot in his vestpocket for a period of a few months during his course in rabbit dissection. It is recalled that this foot was rubbed vigorously before examinations and passed around ceremoniously. The actual routine is vague, but it is quite possible that some nose rubbing ritual may have been involved. In this light, it is interesting to speculate as to the possibility of the acquisition of sensitivity through this method. Guinea pigs have been sensitized by direct inhalation of antigenic dust, and then killed by administration of the same antigen through inoculation.⁷ In humans it has been shown by Figley and Elrod that castor bean dust emitted by a castor oil factory, was the direct cause of many asthma cases in the vicinity of the factory.⁸ In a study of rabbit hair asthma, Ratner reviewed the case of a child with asthma in which the only clue lay in the fact that the child's father worked in a felt hat factory. On further investigation it was found that felt is made from rabbit hair. In the process of his work, particles gathered on his clothing and person. The child reacted positively to a skin test done with dust from the cuff of the father's trousers.⁹

This case serves as an example of the possible danger from use of rabies vaccine without

* Semple vaccine is a sterile 4 per cent emulsion of killed rabies fixed virus (carbolyzed) obtained from the spinal cord of rabbits inoculated intracerebrally with the virus.

proper inquiry into the presence of a hypersensitivity state (and its proper interpretation). Patients about to receive inoculations, should be skin tested, as is done with horse serum injections. In view of the interest displayed in the use of antipneumococcic rabbit serum in lobar pneumonia because of the decreased liability to serum reactions,¹⁰ the possibility of sensitivity to rabbit serum should be kept in mind.

CANCER DEVELOPING IN THE HERNIATED PORTION OF THE STOMACH

ARTHUR L. HOLLAND, M. D., and VICTOR W. LOGAN, M. D., New York City

(Consulting Gastroenterologist, New York Hospital, and Assistant Attending Physician, Roosevelt Hospital, respectively)

JACOBS¹ has recently described a case of cancer developing in the herniated part of the stomach. He was unable to find more than seven other reports, all of which appeared in European journals. The following case is reported for this reason and because it presents the dangers of aspiration pneumonia.

A business executive, aged 74, of German ancestry, came on August 20, 1934, complaining of dysphagia and substernal and epigastric distress during the past two months. In this time he had lost 12 pounds in weight. There was no real pain, only a sense of distress from pressure, usually within two hours after eating. Lying down after a large meal sometimes caused acid regurgitation, but no vomiting.

He had had no other symptoms of relevance in the past. There had been no surgical operations or injuries. The family history was negative.

The essential findings on physical examination were few. He did not appear ill except for some evident loss of subcutaneous fat. The lungs were normal. The heart was slightly enlarged to the left, the superficial arteries thick and beaded. The blood pressure was 105/85. Abdominal examination was negative save for bilateral inguinal hernia. The reflexes were normal. Rectal examination was negative. His weight was 159 pounds.

X-ray study showed, by fluoroscopy, a distortion of the barium stream in the lower third of the chest. Films of this area demonstrated an irregular outline of the terminal esophagus and the upper part of a herniated cardiac end of the stomach. The rest of the gastrointestinal tract was normal.

A stomach tube, passed gently, met with resistance at the 30 cm. mark. When withdrawn the tip was covered with bright red blood and mucus. No free hydrochloric acid was present in the washings of the tube. The urine examination was negative. Blood count gave values of 13 Gm. of hemoglobin and 4,380,000 erythrocytes.

Believing we were dealing with a malignant lesion of the esophagus, secondarily involving the cardia, an esophagoscopy was arranged with Dr. Chevalier Jackson. However, he reported "extensive ulcerative esophagitis, ulcer of the herniated portion of the stomach, transhiatal gastric hernia, peptic esophagitis, chronic gastritis. Other lesions not excluded." Tissue removed for biopsy showed "fragments of mucous membrane bearing resemblance to gastric mucosa. The superficial layers are the seat of hemorrhage, focal necrosis, and mononuclear infiltration. In a few areas, polymorphonuclear leukocytes are seen. Diagnosis: ulcerative esophagitis (F. W. Konzelmann)."

On an ulcer plan the patient gained weight but there was no change in the symptomatology, although at no time in his illness did the gastric symptoms become distressing. A mild anemia was helped somewhat by many small transfusions over the next few months. Suddenly on November 24, 1934, he awoke from a sound sleep at 2:00 A.M. choking. He told his family that his stomach had backed up. There was a severe paroxysmal cough, producing greenish yellow, thick sputum. By morning, the fever had risen to 101° F. with a pulse of 120, and there were signs of consolidation at the right lung base with many rhonchi in both lungs. Within forty-eight hours the patient was out of bed and his cough was decreasingly productive. On close questioning, the patient admitted that for some time, on lying flat in bed, he had had gushes of regurgitated fluid. He had resorted to the use of three pillows. Believing that he had had an aspiration pneumonia, or pneumonitis, from the regurgitation of the stomach contents, while asleep, we elevated the head of the bed by blocks.

Despite this setback the patient went to Florida for the winter and came back in March, 1935, looking well, but films showed more stenosis. The anemia persisted. He had maintained his gain in weight. A second esophagoscopy was done later in the year by Dr. Jackson. The report, dated December 5, 1935, read as follows: "There is a cancer developing in the herniated stomach."

and it is bleeding freely. This was not present when we examined the patient in August, 1934. The other lesions noted in the previous report one year and four months ago are still present. Histologic diagnosis (from biopsy) carcinoma—grade 4."

A course of x-ray therapy was given by Dr. Herendeen at the Memorial Hospital. X-ray films showed no improvement. The patient seemed even worse, clinically. In February, 1936, he had a second pulmonary attack lasting four days. The signs of consolidation were in the left lung base this time. Two further episodes of precisely similar nature occurred in March and May. He made a good recovery from each and with continued transfusions and soft frequent feedings, his blood count at the end of May, 1936, registered 16 Gm hemoglobin and 4,950,000 erythrocytes. His weight at this time was 165 pounds.

In the late summer of 1936 evidence of spinal metastases appeared as a left "sciatica." Films showed a destructive process in the lower lumbar spine. He became progressively weaker and died in the New York Hospital on November 15, 1936, about two and one-half years after the onset of symptoms. At no time did he have much substernal pain, nor did he develop an obstruction. Permission for autopsy was not obtained.

Comment

The extreme rarity of such cases must be more apparent than real. Chevalier Jackson² says "we have seen a few cases in which carcinoma developed in a herniated portion of the stomach, but the proportion is so small that we would not feel justified in saying that the hernia and its secondary pathology were causative factors in starting a malignant process." These cases have not yet been reported according to a private communication from Dr. Chevalier L. Jackson, although he referred to them in a recent talk:

Careful review of cases classed as carcinoma of the terminal esophagus would no doubt show that some were really cancers of the herniated portion of the stomach. With the development of the gastroscope, more interest has been centered on direct visualization of these lesions. (It should be remarked that the closed tube is contraindicated in stenotic lesions near the cardia, and that the Wolff-Schindler gastroscope could not have been used in this case.)

According to Welch's figures,⁴ cancer of the cardiac end of the stomach comprises but 8 per cent of all gastric cancers. Since diaphragmatic hernia is not common, the association of cancer of the cardia and a hiatus hernia will readily be seen to be extremely rare, on the basis of probability.

Speculation will arise as to whether the lesion was a cancer developing in a peptic ulcer. It is interesting that in August, 1934, there was ex-

FIG 1 Cancer of the herniated portion of the stomach

tensive ulceration, gastritis, and stenosis, without evidence of gross carcinoma on direct visualization by a most experienced observer. Furthermore, the biopsy at this time showed no cancer cells. On the other hand, the short history, loss of weight, and anemia already present in August, 1934, are strongly suggestive of neoplasm.

Summary

1 A case of carcinoma developing in the ulcerated herniated portion of the stomach is described.

2 The location and nature of these lesions must be made by endoscopy as well as by x-ray studies of the patients.

3 The patient developed aspiration pneumonia on four different occasions.

CASE OF VENTRICULAR FIBRILLATION FOLLOWING ACUTE CORONARY OCCLUSION

LOUIS H SIGLER, M D , Brooklyn, New York

THAT ventricular fibrillation may follow acute closure of a coronary artery was shown experimentally by Cohnheim and Schulthus-Rechberg¹ as long ago as 1881 and by Porter² in 1894. Wood and Wolferth³ found this disturbance to be the most usual terminal event in experimentation and occurred most frequently when the left posterior circumflex coronary branch was occluded. Harris and Hussey⁴ observed that 15 dogs out of 50 developed ventricular fibrillation within ten minutes after ligation of the anterior descending branch of the left coronary and suspected the condition to be the cause of death in 18 other dogs that died suddenly between three and twenty-four hours after such ligation.

In spite of the frequency of reported observations of ventricular fibrillation in experimental coronary occlusion, there are no reports of clinical cases of this disturbance following occlusion. There are many inferences in the literature that this condition may be the cause of death from occlusion but no actual proved case. For this reason the following case report is of interest.

Case Report

J C., male, 48 years old, mechanic, was seen on October 8, 1936. His father died at 75 years of age from arteriosclerotic heart disease. His mother died at 76 years of age from carcinoma of the esophagus. One brother died at the age of 17 years from typhoid and one sister at 55 from a tumor of the brain. Three brothers and one sister were living and well. The patient's habits were normal, except for constipation. He had been married nineteen years and had one child who was living and well. He had never had any serious illness except for influenza in 1918 when he was compelled to stay in bed three weeks.

On October 8, 1936, he was awakened in the middle of the night by excruciating retrosternal pain radiating to both arms, associated with cold sweat, collapse, vomiting, and air hunger. A total of 1 1/4 gr of morphine had to be given within two and one-half hours to afford relief.

The physical examination revealed a well developed male in a moribund state. His skin was then ashen, cold, and clammy. The respiration was shallow. The heart was slightly enlarged, sounds hardly audible, and the rate could not be determined. The pulse was imperceptible and no blood pressure readings could be obtained. There was some pulmonary edema. He finally sank into deep coma, breathing became labored

- A—Three standard leads, 2 1/2 hours after onset, regular sinus rhythm, rate 136
- B—First lead 2 hours, 45 minutes, sinus slowing, rate 77, sino auricular standstill and nodal escape
- C—Nodal rhythm, rate 71
- D—3 hours, 15 minutes, return to sinus rhythm, rate 94
- E—3 hours, 20 minutes, irregular nodal rhythm interrupted by supraventricular impulses with different spread
- F—3 hours, 48 minutes, short period of ventricular tachycardia, rate 150
- G—Irregular oscillations, rate 255
- H—Four supraventricular impulses
- I—Short oscillatory period, rate 256
- J—Short period resembling H
- K, L, M, N—Continuous undulatory movement, unequal in voltage and appearance, rates progressively diminishing from 221 to 183, 164 and 140, respectively

and slow, and he died three and one-half hours after the onset of the attack. The diagnosis was acute coronary occlusion.

Electrocardiogram—Fig 3A is a portion of the three leads two and one-half hours after the onset. The rhythm is of sinus origin, rate 136 per minute and the PR and QRS conduction time are normal. There is left axis deviation. The QRS complexes are of low voltage with depression and rounding of the R-T segment in the first lead, depression of the S-T segment in the second lead, and elevation and rounding of the S-T segment in the third lead. The T waves are of low voltage, and are positive in the first and second leads and negative in the third lead. All subsequent tracings were taken in the first lead.

Fifteen minutes later, Fig 3B, the rate is 77 per minute and sino-auricular block developed. Nodal escape occurs after about five seconds, which is followed by nodal rhythm at a rate at first of 54 per minute, seen in 3B and later 71 per minute, seen in 3C. In forty-five minutes, Fig 3D, there is a return of a regular sinus mechanism with a rate 94 per minute. In fifty minutes, Fig 3E, nodal rhythm set in again with irregular impulse formation, at a rate of about 112 per minute, followed by a group of complexes with different spread along the bundle branches occasionally interrupted by an impulse of the usual type.

Fifty-eight minutes after the electrocardiographic tracings were begun, continuing for two minutes, including one-half minute after the last breath was taken, a continuous tracing was obtained, part of which is shown in Fig 3F to N. It begins with paroxysmal ventricular tachycardia at a rate of 150 per minute. This is followed by 4 ventricular oscillations, Fig 3G, at a rate of 255 per minute, and then 4 impulses, Fig 3H, resembling somewhat those seen in Fig 3E. This is continued by a short period of oscillations, Fig 3I, at a rate of about 256 per minute which is again interrupted by 5 impulses, Fig 3J, resembling slightly those of Fig 3H. From this point on there are continuous undula-

tions of unequal appearance and voltage. The undulations gradually and progressively slow in rate, increase in length, and diminish in voltage, and there is a marked tendency to partial superimposition. With the higher rates, as in Fig 3K and L where it is 215 per minute, the duration of each complete cycle is approximately 0.27 seconds, and bears a proportional relationship to the whole rate. As the rate slows, the subdivision becomes progressively more unequal.

Summary

A case of acute coronary occlusion is reported with ventricular fibrillation as a terminal event occurring about 3½ hours after the onset of the attack. This appears to be the first reported clinical case of ventricular fibrillation following acute coronary occlusion. Preceding the onset of ventricular fibrillation there were intermittent changes from regular sinus rhythm to sino-auricular standstill, ventricular escape and the development of nodal rhythm, a very brief period of ventricular tachycardia, and finally ventricular fibrillation. The highest rate was about 256 per minute and diminished in voltage at termination. The rate in this case was much lower than in cases of transient recurring ventricular fibrillation reported elsewhere.⁶

APPENDICEAL METASTASIS IN CARCINOMA OF BREAST

H BOLKER, M D, and A L SHAPIRO, M D, Brooklyn, New York

(From the Department of Pathology, Brooklyn Cancer Institute, Kings County Hospital, Brooklyn, and Department of Hospitals, New York City)

SECONDARY involvement of the vermiform appendix from malignant foci elsewhere in the body would not seem an exceedingly rare occurrence. However, careful search through all available standard surgical and pathologic texts as well as the periodical literature of the past three decades reveals, with the two minor exceptions noted below, almost no mention of the condition. A recently published monograph¹ on metastatic lesions refers to only a single reported instance² in a case of extremely generalized carcinomatosis originating in a scirrhous primary carcinoma of the left breast. Here metastases, uniformly described as "secondary,

solid, rarely tubular scirrhous carcinoma" were reported in axillary, cervical, esophageal, gastric, coeliac, lumbar, and mesenteric lymph glands, subperitoneally in Douglas' pouch, of miliary nature in the pericardium, in liver, spleen, adrenals, and right ovary, femur, sternum, ribs, lumbar spine, and multiple likewise in the gastrointestinal tract as submucous gastric infiltration, as submucous nodules scattered through jejunum, more numerous in the lower ileum, and as several submucous secondaries in the appendix.

However, in a short treatise on tumor pathology³ an additional instance was discovered in

an illustration given—no text discussion but described in a brief subtended legend—as a cross section of an appendix showing malignant invasion of its wall from serous coat inward in a case of generalized peritoneal carcinomatous dissemination secondary to a gastric adenocarcinoma. Infiltration was mainly serosal, involving the outer muscularis to a moderate extent as small isolated solid anaplastic cell groups.

The case herein presented likewise stems from a carcinoma of the left breast, in this instance of duct origin and medullary variety. Metastases however, unlike the 2 cases previously noted were far less extensive and considerable necrosis and radiation changes were present in both primary and several treated secondary lesions. On microscopic examination the characteristic primary and secondary picture was one of a poorly cellular fibrous tissue stroma enclosing masses of neoplastic cells in small solid groups or in pseudoglandular arrangement. Individual cells had poorly defined cell boundaries, a moderate amount of eosinophilic cytoplasm, and pycnotic or vesicular nuclei, the latter with irregular nucleoli. Mitotic figures were infrequent.

Case Report

M D Case A-30, B C I, aged 48. Anatomicopathologic diagnosis at postmortem was

- 1 Duct carcinoma of left breast with marked radiation changes, and metastases,
 - A Lymphatic to left axillary, paratracheal, and mediastinal nodes, right and left lungs, tracheal and bronchial walls, parietal pleura and diaphragm
 - B Vascular to scalp, liver, kidneys, adrenals, vermiform appendix, and brain.
- 2 Hypostatic pneumonia, left base. Aortic atherosclerosis. Congenital dilatation of cavum septum pellucidum.

It is noteworthy that careful investigation revealed no other significant pathology of the gastrointestinal tract. The appendix was bound down to the iliac fossa by a peritoneal fold over its anterior surface and measured 12 cm in length, 1 cm distal to the appendiceal base there was a reddish fusiform swelling 2 cm long and 1 cm wide. On section the appendiceal swelling was confined to a uniform increase in thickness of the wall. The lumen was patent, from it several small fecaliths were expressed.

FIG 1

No corresponding ileocecal lymphadenopathy was present. First impression from gross appearances was that the lesion was a coincident carcinoid. However, microscopic examination revealed complete coagulation necrosis of the mucosa with no recognizable residual epithelial or lymphoid elements. Little of the submucosa remained, and this was infiltrated with irregular groups of neoplastic cells, discrete, and with deep staining nuclei, identical with those found in other foci. These extended through the lymphatics of both muscularis and serosa. A scant lymphocytic reaction and occasional small hemorrhages were present in the wall.

Conclusion

A case is reported of a pathologic entity receiving, so far as could be discovered, only two previous descriptions, namely, the involvement of the vermiform appendix by carcinoma from a focus of origin elsewhere. The original lesion in two instances was carcinoma of the left mammary gland, and in the other, gastric adenocarcinoma.

TIME FOR MISSIONARY WORK

The seventy-sixth United States Congress is now in session. It is a safe bet that a national health program proposal, or proposals will be considered during the session.

Therefore, urges the *Ohio State Medical Journal*, missionary work should be done by every physician. Representatives in the Congress

should be interviewed by their physician friends and constituents. The view of the medical profession on medical and health legislation should be presented to them. If personal visits with Congressmen cannot be arranged, a letter should be sent. Disposition of pending health legislation in Congress may depend on what is done now.

Legislative News

Bulletin No 1

THE Legislature convened on Wednesday, January 3, heard the Governor's message and adjourned until Monday night. In the meantime committees were announced. The personnel of those that we are particularly interested in is included in this bulletin.

Inasmuch as the membership of the two bodies is practically unchanged from last year, there will be no delay required for organization as in previous years and the bills that were introduced were immediately referred to committees for consideration. It is important, therefore, that all of our Legislative Committees begin to function promptly. There still remains a number of Societies which have not given us the names of the legislative chairmen or the members of their committees.

May we suggest that each reader of the bulletin immediately take steps toward reviving an acquaintanceship with the legislators representing you so that it will be easy for you to appeal to them for action when it is necessary to oppose or support bills that may be introduced.

Bills Introduced

Senate Int. 4—Williamson, Assembly Int. 16—Hill, authorizes beneficiary of member of State Retirement System who arrived at age of 67 after 21 years' continuous service as village health officer and school doctor, who dies subsequent to April 1, 1939, after application for optional benefit and before time for retirement, to receive benefits under the option upon payment to retirement fund of any moneys paid as death benefit. Referred to the Pensions Committee in the Senate and to the Civil Service Committee in the Assembly.

Senate Int. 10—Williamson, includes female nurses of Army and Navy corps with veterans allowed preference in civil service positions as to removal or transfer. Referred to the Civil Service Committee.

Senate Int. 13—Bewley, Assembly Int. 46—Whitney, imposes a 3 per cent tax on gross receipts on retail sales, services, and facilities after June 30, 1941, where aggregate sales are in excess of \$1,000, revenues so derived to be deposited in separate account to the credit of the State Comptroller in banks he may designate, plan for distribution of moneys to localities on a basis of population is provided, but in no case shall sum to any locality exceed \$15.00 per capita in any calendar year and no moneys accruing shall be distributed to any locality unless the real estate taxes therein shall have first been reduced at least 10 per cent during the last fiscal year. There is created a municipal bond control board in the Audit and Control Department to supervise the issuance of bonds by municipalities. An additional registration fee on motor vehicles, motor cycles, and trailers of 2 per cent is imposed upon first registration or change of ownership, imposes a 1c tax for each 10c or fraction on admission tickets where admission cost is more than 50c, and imposes other amusement taxes. Exemptions include

certain food stuffs and dairy feeds, newspapers, motor fuel, tuition fees to institutions of learning, religious services, services of banks, banking institutions, services supplied by hospitals supported in whole or in part by public funds. Suspends laws relating to supervision by State Social Welfare Department and state aid for local home relief and provides for such relief through local agencies. Appropriates \$500,000 to Tax Department and \$25,000 to Audit and Control Department. Referred to the Taxation Committee in the Senate and to the Ways and Means Committee in the Assembly.

Senate Int. 18—Warner, Assembly Int. 77—Hollowell, makes provision prohibiting alcoholic beverage sales to children apply to children under 18 years of age instead of 16. Referred to the Codes Committees.

Senate Int. 59—Mahoney, Assembly Int. 24—Mailier, increases from five to six the number of members of Assembly to be appointed by Speaker to Commission created to study health of inhabitants of the State. Referred to the Finance Committee in the Senate and the Ways and Means Committee in the Assembly.

Senate Int. 97—Graves, Assembly Int. 79—Allen, prohibits generally the manufacture, sale, or serving of adulterated or misbranded foods. Referred to the Agriculture Committees.

Senate Int. 108—Young, Assembly Int. 195—Vincent, makes provision relating to offenses not bailable by inferior courts apply to the possession or distribution of narcotic drugs, instead of habit-forming drugs, and requires the finger-printing of persons convicted of felony, misdemeanor, and offenses of Art. 22, Public Health Law, which relates to narcotic drugs. Referred to the Codes Committees.

Senate Int. 115—Wicks, creates board in State Education Department for licensing and regulating practice of optical dispensing, and appropriates \$10,000, also relates to licensing optometrists, sale of eyeglasses in stores, and to advertising prices. Referred to the Finance Committee.

COMMENT Senator Wicks had this bill last year. It passed both Houses and was vetoed by the Governor.

Assembly Int. 10—Crews, provides that no person working under compressed air shall be subjected to pressure exceeding 48 pounds, instead of 50 as at present, employer may determine time of each shift when pressure is under 20 pounds provided total for two shifts does not exceed six hours, instead of eight as at present, also changes schedule of shifts and intervals of work for each 24-hour period. Referred to the Labor Committee.

Assembly Int. 94—L. Bennett, provides in actions against New York City or education boards of such city for damages for personal injuries resulting from negligence, the records of both hospital and police departments shall be available to injured person and his attorney. Referred to the New York City Committee.

Assembly Int. 108—McCaffrey strikes out

provision giving injured employee or carrier right to select and pay for physical examination, and requires injured employee to submit to

physical examination as commissioner or board may require Referred to the Labor Committee

Bulletin No 2

THE Committee is considering Wednesday, February 7, as the date for the next annual conference of County Society Legislative Chairmen. It is suggested that the chairmen set aside this date, and the Committee wishes also to suggest that the chairmen of the Legislative Committees of the Auxiliaries will be welcome to attend this conference if they care to do so. The conference will be held in Albany and a later announcement will name the hour and hotel.

Bills Introduced

Senate Int 134—Warner, Assembly Int 152—Milmoë, regulates sale, distribution, and possession of fireworks by local authorities, permits being restricted to public display, local ordinances are superseded and certain exceptions are made. Referred to the Codes Committees.

COMMENT Senator Warner had this bill last year but it was killed in committee. This year several bills similar in nature have been introduced. The Medical Society of Onondaga County a few years ago recommended to the Syracuse authorities that a restriction be placed on the sale of fireworks, and later the Medical Society of the County of Albany recommended to the City of Albany that a similar ordinance be enacted prohibiting the sale of fireworks in the city. This has operated effectively for several years, but merchants selling fireworks have circumvented the law by erecting temporary booths and stands just outside the city limits a few weeks before the Fourth of July each year. We are approving this bill.

Senate Int 167—Phelps Assembly Int 161—Walsh strikes out the provision which permits carrier under Workmen's Compensation Law to select physician for examination of injured employee. Referred to the Labor Committees.

COMMENT The Law at present requires an injured employee to submit to such physical examination as the commissioner or the board may require" and gives permission to the employee or carrier to select physicians to participate in the examination. The amendment would deprive the carrier of this opportunity. The Committee feels that both parties should have the opportunity of selecting physicians to participate in the examination but if either the carrier or the employee does not name a physician to participate, then the other should not be permitted to do so either, in other words, if there is to be participation in the examination both parties should be represented or neither.

Senate Int 199—Desmond, creates a commission to study problem of trichinosis in cooperation with State Health and Agriculture Departments, and appropriates \$25,000. Referred to the Finance Committee.

Senate Int 240—Young, permits sale of narcotic drugs to a physician or surgeon licensed in other state, territory, or District of Columbia or to a retired commissioned medical officer of U S Army, Navy, or Public Health Service employed upon a ship or aircraft. Referred to the Health Committee.

COMMENT This amendment revises the State law so that it may read in accordance with the Federal law.

Senate Int 258—Hastings, Assembly Int. 323—C D Williams, authorizes school district trustees, as well as education boards and union free school districts, to furnish instruction for physically-handicapped children, including remedial instruction, and provides for apportionment of State moneys for aid of common schools to teachers giving such instruction. Referred to the Educational Committees.

COMMENT This amendment is based on findings reported by the Commission which is making a study of the condition of the deaf and hard-of-hearing children in the State.

Senate Int 304—Martin, establishes in State Labor Department a division for the employment, training, and welfare of the deaf and for combating all unfair discrimination, and appropriates \$10,000. Referred to the Labor Committee.

Senate Int 310—Hastings, Assembly Int. 322—C D Williams, requires every physician nurse parent or guardian to report to State Health Commissioner the age and residence of minor under six years who is totally deaf or whose hearing is impaired, in New York City, for adequate care and treatment by appropriate welfare or other agency. Referred to the Health Committees.

COMMENT It is already required in the State outside of New York City that the deaf and hard of hearing shall be reported to the Health Department. This amendment would require the same in New York City.

Senate Int 313—Mahoney, Assembly Int 295—Butler, creates a commission of State Mental Hygiene Commissioner, three physicians to be appointed by the Governor, three Assemblymen and three Senators, to study existing facilities for the care and treatment of feeble minded individuals, and appropriates \$25,000. Referred to the Finance Committee in the Senate and the Ways and Means Committee in the Assembly.

Senate Int 314—Condon, provides that reports of physicians in workmen's compensation cases filed with employer and industrial commissioner, must be verified. Referred to the Labor Committee.

COMMENT This bill relates to the claims of persons injured outside of the State of New York but entitled to compensation or benefits in this State.

Senate Int 355—Gutman, Assembly Int 241—Wagner, creates in the State Labor Department a division in industrial hygiene for investigating and reporting to Industrial Commissioner concerning hygienic conditions in factories, mercantile establishments, mines, tunnels, and other places subject to Labor and Workmen's Compensation Laws for purpose of preventing industrial accidents and controlling health hazards and occupational diseases. Referred to the Labor Committees.

Assembly Int 141—Dollinger, makes it unlawful to sell, possess use, or explode fireworks except on permit of mayor, town supervisor, or other duly constituted licensing authority, for public display by municipality, fair association or other organization with certain exceptions, a bond of not less than \$5,000 to be filed. Referred to the Codes Committee.

Assembly Int 150—Goldstein, provides that injured person or legal representative, in case of death resulting from injuries, shall be permitted to examine hospital records relative to treatment and care. Referred to the Judiciary Committee.

Assembly Int. 183—Holley, creates in the State Health Department a consumers' bureau for registration, advertising, control, analysis, scientific research, education, publicity, manufacture and sale of drugs, cosmetics, or health devices in order to prevent adulteration or misrepresentation. Referred to the Health Committee.

COMMENT This bill has been before the Assembly on two previous occasions.

Assembly Int 188—Holley, provides that persons charged with crime or detained as witnesses in institutions shall be examined for injuries at time arrested, and records shall be kept from time of entrance or transfer to time discharged. Referred to the Penal Institutions Committee.

COMMENT This bill has been before the Legislature on one or two occasions.

Assembly Int. 192—McLaughlin, makes it unlawful to sell, use, or explode fireworks except on permit of fire department or mayor, for public

display by municipality, fair association, or other organization, with certain exceptions. Referred to the Codes Committee.

Assembly Int. 330—Bocca, provides that records of hospital certified by officer in charge may be read in evidence in any court and shall be prima-facie evidence of facts stated therein, if declarations of nonmedical nature or which are explanatory or descriptive are not admissible. Referred to the Codes Committee.

COMMENT It is almost impossible to have a doctor accompany records from a hospital to the court and this amendment would obviate the necessity of a doctor appearing in court by permitting him to file a verified statement.

Assembly Int. 108—McCaffrey, reported in the last bulletin. The Committee has suggested to Mr. McCaffrey that he draft his bill so that either the carrier or the employee is to be represented by his physician at the time the commissioner of labor's examination is made, then shall be represented or neither.

Medical News

County News

Bronx County

The program at the meeting of the Bronx County Medical Society on December 20 included these addresses "The Medical Economic Scene," Nathan Sinai, Ph D, Professor Public Health Administration, University of Michigan, and "Medical Expense Indemnity," Frederic E Elliott, M D, Secretary-Treasurer, Medical Expense Fund, Inc

A series of fortnightly health education meetings are being held in the Mott Haven Health Center every other Thursday at 8 30 P M from January 4 to May 9

The meetings have been arranged in cooperation with the Bureau of Health Education of the Department of Health, the Medical Advisory Committee, the Bronx Tuberculosis and Health Committee, and with the approval and assistance of the Bronx County Medical Society It is the first time the County Medical Society has actively cooperated in such a program to stress the importance of the private physician and the Department of Health in their allied fight to save life. Well-known speakers have been drawn from the Bronx County Medical Society, the Department of Health, and other medical sources

The subjects and dates are as follows Syphilis, January 4, Appendicitis, January 18, Pneumonia, February 1, Diphtheria, February 15, The Dangers of Whooping Cough and Measles, February 29, Tuberculosis, March 14, Trichinosis, March 28, Diabetes, April 11, Acute Rheumatic Fever and Heart Disease in Children, April 25, Cancer, May 9

Broome County

The annual meeting of the Broome County Medical Society was held at the Monday Afternoon Club House, in Binghamton, on December 12 The speaker was Dr David D Rutstein, medical consultant to the Bureau of Pneumonia Control, Department of Health, New York State, instructor of medicine at Albany Medical College and director of the Pneumonia Service at Albany Hospital His subject was "Treatment of Pneumonia," with special attention to the use of sulfapyridine

Cattaraugus County

The new officers of the Cattaraugus County Medical Society are as follows president, Theodore J Holmlund, Cattaraugus, vice-president, Arthur L Runals, Olean, secretary, Leo E Reimann, Franklinville, censors, Henry C. Allen, Gowanda, Hal W Hammond, Franklinville, Leland R Stoll, Randolph, Norman P Johnson, Olean, and J Stewart Fleming, Salamanca

Chautauqua County

The annual meeting of the Medical Society, County of Chautauqua, was held at the Hotel Jamestown on December 13, and the following officers were elected president, Harry E Wheelock, Fredonia, vice-president, Ernest J Kelley, Jr, Jamestown, secretary, Edgar Bieber,

Dunkirk, treasurer, Frederick J Pfisterer, Dunkirk

F J Pfisterer, Dunkirk, C H Richards, Dunkirk, and Walter L Rathbun, Cassadaga, were elected censors Dr D W Buckmaster and Dr Bieber are to be delegates to the State Society meeting

Dr Buckmaster of Jamestown presided at the luncheon which followed and Dr Robert Dinsmore of Cleveland spoke on "The Management of Common Gallbladder Problems"

Dr Paul Garfield Weston, of Jamestown, founder and director of the Jamestown Public Health Laboratory, and prominent in medical activities, died on December 18 at his home, after an illness of nearly a year

He was the author of many papers in medical journals on physiology, pathology, and chemistry Much of the data in these papers has been included in standard medical textbooks

Chemung County

The Medical Society of the County of Chemung has chosen these officers for 1940 president, George R Murphy, Elmira, vice president John H Burke, Sr, Elmira, secretary, Robert J Lawler, Elmira, treasurer, Sven L Larson, Elmira, delegate to State Society, Eliot T Bush, alternate to State Society, John F Lynch, delegate to sixth district, Donald J Tillon, alternate to sixth district, Floyd E Woodhouse Board of censors Floyd E Woodhouse, Alfred John Westlake, and Charles H Erway Board of trustees Arthur W Booth, Charles F Abbott, and J Lee Kinner

Chenango County

The Chenango County Medical Society has chosen these officers for 1940 president, Mat G Boname, Oxford, vice-president, William D Mayhew, Oxford, and secretary-treasurer, John H Stewart, Norwich

The Chenango County Board of Supervisors on December 15, voted to allow doctors twenty five cents a mile, one way, in addition to the regular fee of \$2 per call, on old age relief cases but a few minutes later voted to reconsider and table the motion on finding no funds available.

Cortland County

The following officers for 1940 were elected by the Cortland County Medical Society on December 15 president, Robert Fairchild, vice president, Robert H Brink, secretary, William A Wall, treasurer, Bert R Parsons Censors Stewart A VerNooy, chairman, James Walsh, Charles O Mills, Hugh Frail and C E Chapin

Delaware County

The Delaware County Medical Society held a dinner and annual election at the Elm Tree restaurant in Delhi on December 18

Officers elected are president, Thomas C Monaco, of Walton, succeeding W H F Newman, of Stamford, vice-president, Jerome Ko-

gan, of Stamford, succeeding J H Marsh, and secretary, Orin Q Flint, of Delhi, re-elected

Erie County

The present duty of the medical profession "is to point out the evils of socialized medicine," Dr Carlton E Wertz said on December 18, in his final address as president to members of the Medical Society of Erie County in Hotel Statler. Dr Herbert E Wells, of Lackawanna, was elected to succeed him.

"The fact that our health records are better than ever in spite of the depression and that only Australia and New Zealand, which do not have socialized medicine, excel us does not seem to mean anything to our agitators for socialized medicine," Dr Wertz declared.

Terming the general practitioner "the mainstay of our American democratic system of medicine," Dr Wertz said too much stress has been placed on specialized medicine. "No one questions the need for specialists," he added, but if we are not careful, the general practitioner will be replaced by a medical social worker who will tell the patient what specialist to see."

The following officers were elected for 1940 president, Herbert E Wells, Lackawanna, first vice-president, Nelson W Strohm, Buffalo, second vice-president, Harvey P Hoffman, Buffalo, secretary, Louise W Beams-Hood, Buffalo, treasurer, Roy L Scott, Buffalo, board of censors Charles W Bethune, Buffalo, Joseph D Godfrey, Buffalo, Elmer T McGroder, Buffalo, E Dean Babbage, Buffalo, Francis E Fronczak, Buffalo, chairman on legislation, Joseph C O'Gorman, Buffalo, chairman on public health, John D Naples, Buffalo, chairman on economics, Harold F Brown, Buffalo, chairman on membership, Charles R Borzilleri, Jr, Buffalo, delegates, Carlton E Wertz, Buffalo, Albert A Gartner, Buffalo, John T Donovan, Buffalo, Herbert E Wells, Lackawanna, alternates, Robert E DeCeun, Buffalo, Joseph C O'Gorman, Buffalo, Edward J Lyons, Buffalo, Samuel Varco, Buffalo.

The Medical Union of Buffalo, oldest private medical club in western New York, elected Dr L Maxwell Lockie president in Hotel Buffalo on December 28. He succeeds Dr William J Orr. Other officers are vice-president, Dr Curtis C Johnson, and secretary-treasurer, Dr Nelson W Strohm, elected for his fifth consecutive term. A paper on "The Future of the Gynecologist" was presented by Dr James E King, professor of gynecology, University of Buffalo Medical School.

The Section of Medicine of the Buffalo Academy of Medicine met on December 13, at the Buffalo Museum of Science, Humboldt Park, and heard a paper on "The Diagnosis and Treatment of Meningitis," by Dr Josephine B Neal, clinical professor of neurology, College of Physicians and Surgeons, New York City.

Genesee County

The annual meeting of the Genesee County Medical Society was held at Batavia, on December 13. The program

1 Discussion of laboratory plan, to be presented to the Board of Supervisors

2 Discussion of plan of Medical Expense Indemnity

3 Election of officers president, E G Ribby, Byron, vice-president, Charles M Graney, Batavia, secretary and treasurer, Peter J DiNatale, Batavia. Delegate for two years Peter J DiNatale, Batavia, alternate delegate, Paul P Welsh, LeRoy.

Paper of the day was by Dr Joseph B Loder, Rochester, on "Complications of Pregnancy"—*Reported by P J DiNatale, M D, Secretary*

Greene County

At the annual meeting on October 10, the following officers were elected to the Greene County Medical Society president, Kenneth F Bott, Greenville, vice-president, Herbert Weinauer, Windham, secretary, William M Rapp, Catskill, treasurer, Mahlon H Atkinson, Catskill, chairman legislative committee, Percy G Waller, New Baltimore, chairman public relations committee, William V Wax, Catskill, delegate, William A Petry, Catskill.

Herkimer County

The Medical Society of the County of Herkimer elected these officers for 1940 on December 12 president, George J Frank, 1st vice-president, Harry D Vickers, 2nd vice-president Byron G Shults, 3rd vice-president, Nicholas D Lill, secretary, Fred C Sabin, treasurer, Albert L Fagan, librarian, George S Eveleth. Censors George A Burgin, Harold F Buckbee, James F Gallo, Harry J Sheffield, F B Conterman. Delegate, George A Burgin, alternate, George J Frank.

Jefferson County

The Medical Society of Jefferson County met on December 14, at the Black River Valley Club, with dinner at 6 30 p.m. The program "Reconstructive Surgery," by Forrest Young, M D, Strong Memorial Hospital, Rochester, and at 5 p.m. there was a tumor conference at the Good Samaritan.—*Reported by C A Prudhon, M D, Secretary*

Kings County

Officers of the Medical Society of the County of Kings to serve during 1940 under the leadership of Dr Daniel A McAteer, who was named president-elect a year ago, were elected at the annual meeting on December 19.

Named as president-elect, to take office in January, 1941, was Dr Maurice J Dattelbaum of 263 New York Avenue, who is attending physician at Beth-El Hospital. Dr Philip I Nash, retiring president, presided at the meeting.

Papers were presented during the scientific session by Dr Marion B Sulzberger, dermatologist and syphilologist, of Manhattan, and Dr Samuel M Feinberg, associate professor of medicine and chief of the allergy department at Northwestern University Medical School.

Among the officers elected for 1940 were Robert M Rogers, vice-president, Thomas B Wood, secretary, Benjamin M Bernstein, associate secretary, Irwin E Sins, associate treasurer, Jacques C Rushmore, directing librarian, and Edwin P Maynard, Jr, associate directing librarian and curator.

John L Bauer, Thos M Brennan, and Philip Nash were chosen trustees for five years. Dr Albert F R. Andresen was named trustee for two years to fill an unexpired term.

Dr Hyman I Teperson, Brooklyn radiologist, was inducted as president of the East New York Medical Society at its thirtieth annual installation exercises on January 8 at the Temple Auditorium, Rochester Avenue and St John's Place. Dr Harry Apfel, one of the founders of the society and its first president, officiated.

One of the oldest medical organizations in Brooklyn, the East New York Medical Society has a membership of over four hundred doctors from the East New York, Brownsville, and Bedford sections.

Other officers installed William Levine, Morris Ant, vice-presidents, Max Dannenberg, treasurer, Mortimer M Kopp, secretary, Harry Beller, recording secretary.

The Williamsburgh Medical Society of Brooklyn held its 25th meeting on January 8 at the Leon Louria Memorial Auditorium of the Jewish Hospital, St Mark's and Classon avenues. Commander Frank W Ryan of the U S N Medical Corp and Dr Edgar D Congdon, professor of anatomy at L I College of Medicine, were the guest speakers.

Lewis County

The board of supervisors of Lewis County have authorized the formation of a county laboratory as a branch of the state laboratory. Dr E Dalton, of Beaver Falls, and Dr T A Lynch, of Lowville, have been appointed the two physicians on the board of managers.

Monroe County

New advances in the attack of science on anemia through the use of radio-iron are reported by Dr George H Whipple, dean of the University of Rochester School of Medicine, and Nobel prizewinner for research in anemia, and Dr Paul F Kahn, also of the university.

The two scientists revealed before the American Association for the Advancement of Science at Columbus that with radio-iron they are able to trace accurately the rate of formation of hemoglobin, the red matter of the blood which carries oxygen from the lungs to all parts of the body. Anemia results when this hemoglobin formation does not occur normally.

The university's cyclotron, or 'atom smashing' machine, again has played a part in medical science's battle against disease, the doctors reported, according to the Associated Press. By the atomic bombardment of iron with the cyclotron radioactivity or emission of radium-like particles was developed.

By the use of sensitive instruments which count those particles the formation of hemoglobin and its rate of survival can be determined. The full use of the method in the treatment of disease has not yet been determined, said Doctors Hahn and Whipple. Doctor Hahn is an instructor in chemistry and experimental pathology.

Montgomery County

Dr William R Pierce, of Amsterdam, who died on November 9 of coronary sclerosis aged 78, had practiced medicine for 55 years and was secretary of the County Medical Society for 35 years.

New York County

Drastic cuts in the budget of the New York Academy of Medicine, 2 E 103rd St., have been

forced by "financial difficulties," it was reported by Dr Malcolm Goodridge, president, at the organization's annual meeting on January 4.

Activities have had to be curtailed in every department, Dr Goodridge said, and five of the staff of eighty employees have been released.

Dr Herbert B Wilcox, director of the Academy, revealed that reserve funds have been dipped into during the last two years because of recurring deficits.

To protect children, and adults as well, from tuberculosis, syphilis, and other diseases which might be acquired through maids and other household workers, The Bureau of Part Time Work, 1440 Broadway, a noncommercial organization and a member of the Welfare Council, is starting a movement to have domestic servants receive an x-ray examination of the lungs, a Wassermann blood test, and a complete physical examination semiannually, it is announced by Miss Eleanor Adler, founder of the Bureau.

Dr George Emerson Brewer, cancer specialist, regarded as one of America's outstanding surgeons, who retired in 1927, died on December 24 in the Harkness Pavilion of the Columbia Presbyterian Medical Center. He was 78.

He always was deeply interested in research and with Dr Joseph A Blake he developed the research laboratory of surgical pathology at the College of Physicians and Surgeons in 1904 and 1905. He was the author of many articles on anatomical and surgical conditions and wrote a *Text Book on Surgery*, published in three editions by Lea & Febiger, and *Surgical Diagnosis* published by Appleton & Co.

In the World War he was director of Base Hospital No 2, which relieved General Hospital No 1 of the British Expeditionary Forces. Later he was consulting surgeon of the 42d Division, A E F, and chief consultant in surgery of the First Corps, and the First Army. He was cited by Gen John J Pershing for especially meritorious and conspicuous service in the battles of Château Thierry, St. Mihiel, and the Argonne.

Dr Robert L Lewis, professor emeritus of clinical otolaryngology at the College of Physicians and Surgeons, Columbia University, since April, died on December 20, of pneumonia at his residence, 40 E 64th Street. He was 77 yrs old.

Dr Lewis had been a professor in the department of ear, nose, and throat diseases at Columbia for thirty-one years.

Niagara County

The annual dinner meeting of the Medical Society of the County of Niagara was held in the Niagara Hotel ballroom at Niagara Falls on December 12. The guest speaker, Ernest Robert Rosse, discussed "The Safety Valve of Sanity." Officers were elected for 1940.

Oneida County

Early diagnosis is the greatest enemy of intestinal cancer, Dr Carl Eggers, professor of clinical surgery, Columbia University, told the Utica Academy of Medicine at its meeting on December 21.

He spoke of the importance of x ray examinations and deplored the fact that the cost prevents many patients in the limited income class from

finding out whether or not vague symptoms mean cancer

Dr Robert Lindsay, Old Forge, gave the preliminary paper, "Medical Practice in the Adirondacks"

Onondaga County

Members of the Syracuse Academy of Medicine elected Dr P K. Menzies to its presidency at their annual meeting on December 19, in the University Club, at which Dr Brooks W McCuen, retiring president, presided

Other officers named were Donald S Childs, vice-president, Floyd R Parker, secretary, Clifford E McElwain, treasurer, George S Reed, Floyd Burrows, and R.S Farr, trustees for one year, and McCuen, Leo E Gibson, and Herbert C Yeckel, council members for one year

Announcement was made that Dr Wardner D Ayer had won the academy's annual prize essay contest award of \$50 for his paper on "Twenty Years in Neuro-Surgical Pathology in Syracuse," given at the academy's May meeting

Dr Brewster C Doust is the new president of the Onondaga County Medical Society The JOURNAL regrets its error in printing that Dr H Burton Doust, the Commissioner of Health of Syracuse, had been named to that office.

Otsego County

The annual meeting of the Otsego County Medical Society was held on December 13, at the Homer Folks Hospital in Oneonta and the following officers were elected for 1940 president, Ralph Horton, vice-president, Charles C McCoy, treasurer, Frederick E Bolt, secretary, Floyd J Atwell, censor, Earl C Winsor, delegate to State Society, Floyd J Atwell, alternate John H Powers

Queens County

Dr James R Reuling, of Bayside, has been re-elected to head the Queensboro Tuberculosis and Health Association during 1940 George Lawrence, M D, of Flushing, and Harold H Mitchell, M D, of Astoria, are among the newly elected directors

Dr Joseph Baum, of Far Rockaway, was given a testimonial dinner at Lawrence Village Park Clubhouse on December 18 in celebration of his 70th birthday Dr Baum recently retired as chairman of the medical staff of St Joseph Hospital He was succeeded by Dr Alfred Calvelli, who acted as toastmaster at the dinner

Drs William K. Rogers, of Flushing, and Vincent Juster, of Jamaica, are the treasurer and assistant treasurer respectively, of the Queens County Medical Society for 1940 Unfortunately incorrect names for these offices were published in the January 1 issue which the JOURNAL regrets very much

Rockland County

The Medical Society of the County of Rockland held its annual meeting and dinner on December 6 at the Hotel St. George, Nyack.

The principal officers elected for 1940 are president, Russell E Blaisdell, Orangeburg, vice-president, Matthew J Sullivan Haverstraw, treasurer, Dean Miltimore, Nyack, and secretary, William J Ryan, Pomona.

Dr George M Richards was elected chairman of the board of censors for 1940 and 1941, with Dr Pomcrantz as vice-chairman Other members include Dr E Armand Scala, Dr J C Dingman, Dr Sengstacken, and Dr Edwyn O'Dowd Dr Stephen R. Monteith was named delegate to the State Medical Society for 1940 and 1941, with Dr Ryan as alternate.—*Reported by William J Ryan, M D, Secretary*

Schenectady County

At the meeting of the Schenectady County Medical Society on January 2, in the Auditorium of the Nurses Home of the Ellis Hospital a paper was presented on "Benign and Malignant Tumors of the Larynx Observations of General Interest on the Diagnosis and Treatment," by Gabriel Tucker, M D, Professor of Bronchology, Esophagology, and Laryngeal Surgery, Graduate School of Medicine, University of Pennsylvania

Schoharie County

At the annual meeting of the Schoharie County Medical Society, held in the W H Golding Central School on October 10, the following were elected officers for 1940 president, David W Beard, Cobleskill, vice-president, R. G S Dougall, Cobleskill, secretary, Herbert L Odell, Sharon Springs, treasurer, Duncan L Best, Middleburg, censor, Joseph F Duell, Jefferson, delegate to State Society, David W Beard, Cobleskill.—*Reported by Herbert L Odell, Secretary*

Schuyler County

The new officers of the Schuyler County Medical Society are as follows president, Paul F Willwerth, Montour Falls, vice-president, Joseph Y Roberts, Watkins Glen, secretary and treasurer, Oakley A Allen, Watkins Glen. Delegate, Jos Y Roberts, Watkins Glen, alternate, Paul F Willwerth, Montour Falls — *Reported by O A Allen, M D, Secretary*

Seneca County

The officers of the Seneca County Medical Society for 1940 are president, Robert F Gibbs, Seneca Falls, vice-president, Arthur F Baldwin, Waterloo, secretary and treasurer, Duane B Walker, Waterloo

Ill for some time, Dr Ephriam W Bogardus, 84, well-known practicing physician of Seneca County for more than fifty years, died on December 16 in his home, 218 Lewis street, Geneva

He was president of the County Medical Society in 1889

Critically ill for several weeks, Dr John F Crosby, 81, dean of the Seneca County medical profession, died on January 2 at his home on the Lake Road, three miles east of Seneca Falls

He was president of his County Medical Society several times and was formerly a member of the State legislature.

He was president of the Village of Seneca Falls in 1892 and 1893 and served as mayor in 1933 and 1934 At one time he was chief of the Seneca Falls Fire Department and for many years was a member of the Old Salsby Hose Company

Tioga County

Dr Charles J V Redding, of Owego, was elected president of the Tioga County Medical

Society for the ensuing year at the annual dinner meeting on December 5, at the Green Lantern Inn in Owego. Other officers named are vice-president, J B Schamel, Waverly, secretary, Ivan N Peterson, Owego, censors, F A Carpenter, Waverly, and William B Gregory, Owego.

The principal speaker at the meeting was Dr Charles Post, professor of medicine at the Syracuse University School of Medicine. He gave an illustrated lecture on "Treatment of Pneumonia."

Tompkins County

At the annual meeting of the Tompkins County Medical Society held December 19, the following officers were elected: president, Hudson J Wilson, Ithaca, vice-president, Dean F Smiley, Ithaca, secretary-treasurer, Willets Wilson, Ithaca, delegate, Norman S Moore, Ithaca, alternate, Dean F Smiley, Ithaca, censors, Henry E Mernam, Ithaca, Henry B Sutton, Ithaca, Leo P Larkin, Ithaca, Henry W Ferris, Ithaca, William L Seil, Newfield.

Ulster County

Employment of five public health nurses at a gross cost of \$3,000 each, was asked of the Ulster County board of supervisors at its meeting on December 20.

The request was made by Dr Virgil B DeWitt of New Paltz and Dr Jay R Lockwood of Highland, representing the Ulster County Medical Society which has given unanimous approval to the plan. At the same time a communication was read from Mary H Oxholm of Esopus, president of the Public Health Nursing Committee of the Town of Esopus, saying that unless nurses are employed the "committees in the various towns must cease to function and we feel it would be many years before interest in public health could be roused again."

Officers for 1940 are as follows: president, William S Bush, vice-president, John B Krom, secretary, Clarence L Gannon, treasurer, Chester B Van Gaasbeek, delegate to the State Medical Society, Frederic W Holcomb. All are from Kingston.

Wayne County

The new officers of the Wayne County Medical Society for 1940 are as follows: president, Charles Steyaart, Lyons, 1st vice-president, James L Davis, Newark, 2nd vice-president, George W Pasco, Wolcott, secretary and treasurer, James L Davis, Newark, delegate, Ralph Sheldon, Lyons, alternate, Sam W Houston, Wolcott, board of censors, Arthur Besmer, Marion, George S Allen, Clyde, Myron E Carmer, Lyons.

Westchester County

Dr Henry J Vier, outgoing chief-of-staff of St Agnes Hospital and recently elected president of the Westchester County Medical Society, was honored with a testimonial dinner on December 27, at the Westchester Country Club. Fifty-five members of the St Agnes staff were present.

Dr Vier was presented with a gold fountain pen for his work as president of the staff, a position he has held for two years. He is succeeded by Dr Harris W Campbell, recently elected staff president.

Wyoming County

The new officers of the Wyoming County Medical Society for 1940 are as follows: president, G Stanley Baker, vice-president, Clifford H. Harville, secretary-treasurer, Oliver T Ghent, delegate to state medical society, Henry S Martin, alternate delegate, Richard B Bean.

Deaths of New York State Physicians

THAT TELLS THE STORY

A recent announcement by Dr Richard A Bolt, director of the Cleveland Child Health Association, is of more than passing significance.

Dr Bolt reported that among the 2,500 women

who completed the prenatal education classes held by the association in cooperation with the Cleveland Academy of Medicine during the first six months of 1939, there was not a single fatality from childbirth.

The Woman's Auxiliary

To the Medical Society of the State of New York

Dear Auxiliary Members

A new year with its new responsibilities, its new problems, and its new opportunities, is upon us. There are new health problems to solve, there is new work to be done for the suffering victims of unjust warfare across the ocean, but nearer and far more vital to each and every one of us is the threat of socialized medicine that hangs like the sword of Damocles over the heads of our husbands. These men with their ideals, their code of ethics, their devotion to their beloved profession have not the time to fight this threat. We, the loyal wives, must do our utmost to see that the slender hair on which their future and ours hangs shall not be broken.

Let us all make a new year's resolution that we shall thoroughly acquaint ourselves with the provisions of the Wagner Act and become familiar with the subject of socialized medicine so that by our knowledge and our enthusiasm we may become a mighty force. Surely eighteen hundred New York State Auxiliary members, spread throughout twenty-two counties, can exert a great influence in forming public opinion! We must do our best!

MARY T TOWNE, President

Cayuga County

The Woman's Auxiliary held the first meeting of the new year January 18, with the new president, Mrs. George Sincerbeaux, presiding. The members were gratified to learn that they had been responsible for much happiness at Christmas by their gifts to the "Home for Convalescing Children."

Public health work done in the county was discussed by Dr. George B. Adams. Chairmen of standing committees were appointed.

Fulton County

At the first regular meeting of the new Fulton County Auxiliary several new members were added to the roll. Committee chairmen were appointed to choose their own committees.

Kings County

At the annual meeting of the Woman's Auxiliary the following officers were elected: president, Mrs. Milton Bergmann, first vice-president, Mrs. Henry Dangler, second vice-president, Mrs. Robert Barber, secretary, Mrs. Morris Henry, associate secretary, Mrs. William de Frane, treasurer, Mrs. Charles Fisher, associate treasurer, Mrs. Maurice Dattlebaum.

At the regular meeting in January, Mrs. Clifton Dance, chairman of legislation, gave a talk on "Current Medical Legislation." Mrs. William de Frane discussed a current article from *Hygea*. Mrs. Edwin Griffin discussed plans for a luncheon to be held in March at the Hotel Waldorf to commemorate the fifth anniversary of the Auxiliary.

Mrs. John Bauer exhibited a petit point chair set to be sold at the state convention for the benefit of the Physicians' Home.

Mrs. George Smith, program chairman, introduced the speakers who were guests at this meeting. Dr. George Merrill whose subject was "Allergy", Mrs. Nelson Mules Holden who gave a very interesting book review of *Miss Susie Slagle* by Augusta Tucker.

Nassau County

Wives of Nassau County physicians could make an excellent showing on some of the current radio quiz programs, judging from their record at the annual Christmas party of the Nassau County Auxiliary held in Mineola. The program was arranged by Mrs. Willard J. Lee. Mrs. Louis Van Kleek was Santa Claus and presented a gift to each who answered a question correctly. Fifteen members of the Plandome Singers Club gave a beautiful music program. Mrs. Leslie Baker sang a group of solos.

Onondaga County

The Onondaga County Auxiliary planned a novel program for their dinner-dance party held in December. A comical skit was presented and bridge games as well as dancing were enjoyed.

At the January meeting Mrs. Edgar Neptune, the new president, presided. The drive to obtain subscriptions to *Hygea* is to be continued. The guest speaker at this meeting was Dr. Raymond Graham whose subject was "The History of Medicine in Onondaga County."

Oswego County

The Oswego County Auxiliary held a dinner meeting in December. Announcement was made by the president, Mrs. John Mason, of committee chairmen. It was decided to create a charity fund to bring Christmas cheer to needy families. The guest speakers were Miss Isabelle Murray and Miss Alice Swackhamer, county health nurses, who discussed their work in the county, taking as their subject, "Why Public Health Nurses?"

Rensselaer County

Women of the Rensselaer County Auxiliary were guests of Albany County Auxiliary in December at a luncheon meeting and bridge party. The principal speaker was Mrs. Luther Kice, president-elect of the State Auxiliary.

At the annual meeting held in December the following officers were elected: Mrs. Stephen Curtis, president, Mrs. John Ennen, first vice-president, Mrs. Walter McShane, second vice-president, Mrs. John Rainey, president-elect, Mrs. Eugene Connolly, recording secretary, Mrs. F. J. Fagan, assistant recording secretary, Mrs. A. J. Hambrook, treasurer, Mrs. John Carroll, assistant treasurer, Mrs. Leo Weinstein, corresponding secretary, Mrs. R. E. DeFries, assistant corresponding secretary.

The auxiliary voted to become a unit member of Troy Council of Social Agencies. Mrs. Peter Harvie explained the work of the council. The annual Christmas party was held at the close of the meeting.

Malpractice—Sufficiency of Evidence

5711111 1
-129111 21
2111 31
11111 011
11111 11

IN A case recently decided by the highest court of one of the western states an interesting situation was presented involving the question of the sufficiency of the proof to hold the defendant guilty of malpractice.

The plaintiff in the action brought suit to recover damages for personal injuries against Doctor G, a physician who had operated upon her and advised concerning her care after the operation. The principal charges were that he had improperly diagnosed plaintiff's condition as a malignancy, and had improperly advised deep x-ray therapy treatments which had proved harmful to the patient.

The case was fully tried, and during the trial defendant introduced the testimony of various doctors in support of the methods followed by him, but the question before the Appellate Court resolved itself into whether the plaintiff's witnesses had adduced sufficient proof to support a finding that defendant was guilty of malpractice. For that reason the testimony of defendant's witnesses was not to any extent under consideration by the Appellate Court.

The plaintiff's witnesses in addition to herself and members of the family, were three physicians, one an x-ray man, and two of them practitioners who took over the care of the patient following Doctor G. The facts, as developed by the testimony of those witnesses, must be summarized in some detail.

It seems that the plaintiff had given birth to a dead child at full term, following which she was under the care of a Doctor R. About six months after the delivery Doctor R. took her to Doctor G, the defendant, for consultation. He was given a history by the patient of pain on the left side for about three weeks and pressure upon standing which caused her to vomit. Doctor R., in giving his history, informed Doctor G of her blood pressure, and temperature which had been elevated. Thereupon Doctor G examined the abdomen, both externally and vaginally. Doctor G told the patient that she had a tumor about the size of a small grapefruit, the nature of which he would not know until he operated.

A few weeks Doctor G performed the operation which was contemplated. The hospital record indicated the preoperative diagnosis to be "tubo-ovarian abscess" and the postoperative diagnosis recorded by defendant was "retro-peritoneal sarcoma. Adhesions to iliac vessels, ureter, etc., are so dense as to make removal impossible." According to the testimony of the plaintiff she was told by the surgeon that he had been unable to do a great deal at the operation and that after recovery from the shock of the operation other methods of treatment should be

resorted to. The testimony of the mother of plaintiff indicated that she had witnessed the operation and had seen Doctor G take out two pieces of tissue from the tumor. It appeared from the records of the hospital that the pathologist had reported a diagnosis from laboratory examination of "cellular neurofibroma." It was conceded that the said condition was one kind of cancer.

A few weeks after the operation the plaintiff told Doctor G that she felt about the same as before the operation, and he then advised and arranged for deep x-ray treatments which were administered by another physician.

It seems that thereafter peritonitis developed for which an operation was performed, and that she was obliged to undergo treatments and care for "a bowel trouble" which she sustained. For these conditions several physicians cared for her, including a Doctor H and a Doctor J.

Doctor T, a roentgenologist, was called as a witness by the plaintiff, and stated that he had taken x-ray pictures of the patient about six months after Doctor G's operation. He said that he could not see any evidence of malignancy at the time, but conceded that x-ray treatments might have rendered it impossible to make such a reading of the x-rays, even though there might have been a previously existing condition of sarcoma. His testimony indicated that the principal methods of diagnosing sarcoma were the use of x-ray pictures, and of laboratory work.

Doctor H, when called as a witness, gave testimony that when he saw the patient he found no evidence of sarcoma, or of whether she had ever had sarcoma. He enumerated various approved tests in aid of such a diagnosis including biopsy, x-ray, and blood examinations.

The witness upon whom plaintiff chiefly relied as establishing a prima-facie case against Doctor G, was Doctor J. The latter contended that the plaintiff never had had a sarcoma and was critical of the diagnostic methods which the defendant had used. However, the Appellate Court in reviewing the case rejected the contention that he established a sufficient case for submission to the jury, saying in part concerning Doctor J:

"He criticized the procedural methods used by the defendant before advising an operation, claiming that all probability of the existence of a non-malignancy should have been eliminated by the use of various methods which he outlined, before performing an operation. But the insufficiency of that testimony, on the issue here, is that Doctor G did not diagnose the trouble as a malignancy, prior to the operation. On the contrary, his diagnosis was that the patient had an abscess. Doctor J says she did not have a sarcoma and Doctor G came to the same conclusion even though he didn't use all the tests which Doctor

J thinks he should have used to eliminate the probability of nonmalignancy.

We find no evidence to support an allegation that proper care was not taken in making the tentative diagnosis or that the recommendation of an operation after such diagnosis constituted malpractice, or that the operation was not performed in an efficient and professional manner."

In ruling out the contention that it was improper to advise x-ray treatments, the Court said

Plaintiff's evidence certainly does not tend to support any allegation that the employment of biopsy or reliance placed in laboratory diagnosis of malignancy constituted malpractice. On the contrary, it might be urged that he would have been guilty of malpractice if he had not had such microscopic examination made and given weight to the report.

'Doctor G's own postoperative diagnosis being that the plaintiff had a malignant growth, and that it was inoperable, and the microscopic test confirming the diagnosis, is there any testimony here that the use of x-ray treatments constituted malpractice? We find none. Plaintiff's witnesses testified to the contrary. Doctor T testified 'If there had been one (sarcoma) before the plaintiff had received this course of x-ray treatments,

it is possible it would have disappeared and I couldn't see it here'

"He also testified, as heretofore noted, that the tendency of x-ray treatments is to stop the activities and growth of malignant cells."

In directing that judgment should be entered in favor of defendant, reversing the ruling of the Trial Court which had been favorable to plaintiff, the Appellate Court summarized the general rules applicable to malpractice actions as follows

'A physician or surgeon is not a guarantor of the correctness of his diagnosis or of the efficacy of the treatments prescribed, but he is required to exercise the degree of skill and learning ordinarily possessed and exercised under similar circumstances by the members of his profession in good standing and to use ordinary and reasonable care and diligence and his best judgment in the application of his skill to the case. Negligence cannot be presumed from the mere failure to obtain the best results. To establish liability there must be competent testimony that there was lack of care or that approved procedure and methods were not followed and the general rule is that the negligence in the treatment which is claimed must be shown by medical witnesses called as experts, that it must come from those qualified by education, training and experience to give it'

Treatment of Fractured Leg

A PHYSICIAN who specializes in orthopedic surgery was called to attend a woman about 45 years of age, who had sustained a fractured leg. He examined her and found her suffering from a fracture of the tibia and fibula involving the ankle joint. X-rays were immediately taken which confirmed the diagnosis and the evening of the same day under a general ether anesthetic the fracture was reduced by manipulation and a plaster-of-paris cast was applied from the toes to the knee. X-rays taken the next day showed the bones to be in good alignment and the patient progressed satisfactorily. She was discharged from the hospital during the fourth week.

At the end of six weeks the plaster-of-paris cast was removed and both position and motion were progressing favorably. The doctor advised the patient to begin light weight bearing with crutches and gradually to increase the same.

The patient following the removal of the cast returned to the doctor's office three times a week for physiotherapy treatments for a period of about eight weeks. The doctor found that the patient was refusing to bear weight on the injured leg and suspected her of saving the same for the purpose of maintaining the value of her claim against the party responsible for the original injuries.

The doctor last saw the patient about eight weeks after her discharge from the hospital at

which time she left the State of New York. When he last saw her he gave her a letter for her to present to any doctor subsequently caring for her in which he outlined the treatment he had rendered. Her condition at that time was satisfactory.

A malpractice action was instituted against the doctor two years and two months after he last saw the patient, in which the claim was made he had improperly reduced the fracture and cared for the leg so as to leave the bones in an improper position and to cause the foot to be displaced backward.

The defendant in answering the complaint denied all charges of malpractice and in addition pleaded the two year Statute of Limitations applicable to malpractice actions.

Prior to the time the case would be reached for trial, defendant's attorney attempted to obtain a bill of particulars of the complaint, requiring among other things the plaintiff to specify the dates of the alleged malpractice on the part of the defendant. At that point in the lawsuit plaintiff apparently realized that the action was in fact barred by the Statute of Limitations for no bill of particulars was served and the defendant obtained an order precluding the plaintiff from testifying with respect to the alleged negligence complained of and shortly thereafter the action was discontinued.

ALUMNI DAY—NEW YORK UNIVERSITY COLLEGE OF MEDICINE

The Alumni Association of the New York University College of Medicine announces that the alumni day exercises will be held on

Washington's Birthday, February 22. The scientific program will be published in the February 15 issue.

Counsel, Medical Society of the State of New York

Malpractice—Sufficiency of Evidence

IN A case recently decided by the highest court of one of the western states an interesting situation was presented involving the question of the sufficiency of the proof to hold the defendant guilty of malpractice.

The plaintiff in the action brought suit to recover damages for personal injuries against Doctor G, a physician who had operated upon her and advised concerning her care after the operation. The principal charges were that he had improperly diagnosed plaintiff's condition as a malignancy, and had improperly advised deep x-ray therapy treatments which had proved harmful to the patient.

The case was fully tried, and during the trial defendant introduced the testimony of various doctors in support of the methods followed by him. But the question before the Appellate Court resolved itself into whether the plaintiff's witnesses had adduced sufficient proof to support a finding that defendant was guilty of malpractice. For that reason the testimony of defendant's witnesses was not to any extent under consideration by the Appellate Court.

The plaintiff's witnesses in addition to herself and members of the family, were three physicians, one an x-ray man, and two of them practitioners who took over the care of the patient following Doctor G. The facts, as developed by the testimony of those witnesses, must be summarized in some detail.

It seems that the plaintiff had given birth to a dead child at full term, following which she was under the care of a Doctor R. About six months after the delivery Doctor R. took her to Doctor G, the defendant, for consultation. He was given a history by the patient of pain on the left side for about three weeks and pressure upon standing which caused her to vomit. Doctor R., in giving his history, informed Doctor G of her blood pressure, and temperature which had been elevated. Thereupon Doctor G examined the abdomen, both externally and vaginally. Doctor G told the patient that she had a tumor about the size of a small grapefruit, the nature of which he would not know until he operated.

A few weeks Doctor G performed the operation which was contemplated. The hospital record indicated the preoperative diagnosis to be "tubo-ovarian abscess" and the postoperative diagnosis recorded by defendant was "retroperitoneal sarcoma. Adhesions to iliac vessels, ureter, etc., are so dense as to make removal impossible." According to the testimony of the plaintiff she was told by the surgeon that he had been unable to do a great deal at the operation as he found it impossible to remove the growth, and that after recovery from the shock of the operation other methods of treatment should be

resorted to. The testimony of the mother of plaintiff indicated that she had witnessed the operation and had seen Doctor G take out two pieces of tissue from the tumor. It appeared from the records of the hospital that the pathologist had reported a diagnosis from laboratory examination of "cellular neurofibroma." It was conceded that the said condition was one kind of cancer.

A few weeks after the operation the plaintiff told Doctor G that she felt about the same as before the operation, and he then advised and arranged for deep x-ray treatments which were administered by another physician.

It seems that thereafter peritonitis developed for which an operation was performed, and that she was obliged to undergo treatments and care for "a bowel trouble" which she sustained. For these conditions several physicians cared for her, including a Doctor H and a Doctor J.

Doctor T, a roentgenologist, was called as a witness by the plaintiff, and stated that he had taken x-ray pictures of the patient about six months after Doctor G's operation. He said that he could not see any evidence of malignancy at the time, but conceded that x-ray treatments might have rendered it impossible to make such a reading of the x-rays, even though there might have been a previously existing condition of sarcoma. His testimony indicated that the principal methods of diagnosing sarcoma were the use of x-ray pictures, and of laboratory work.

Doctor H, when called as a witness, gave testimony that when he saw the patient he found no evidence of sarcoma, or of whether she had ever had sarcoma. He enumerated various approved tests in aid of such a diagnosis including biopsy, x-ray, and blood examinations.

The witness upon whom plaintiff chiefly relied as establishing a prima-facie case against Doctor G, was Doctor J. The latter contended that the plaintiff never had had a sarcoma and was critical of the diagnostic methods which the defendant had used. However, the Appellate Court in reviewing the case rejected the contention that he established a sufficient case for submission to the jury, saying in part concerning Doctor J:

"He criticized the procedural methods used by the defendant before advising an operation claiming that all probability of the existence of a non-malignancy should have been eliminated by the use of various methods, which he outlined, before performing an operation. But the insufficiency of that testimony, on the issue here, is that Doctor G did not diagnose the trouble as a malignancy, prior to the operation. On the contrary, his diagnosis was that the patient had an abscess. Doctor J says she did not have a sarcoma and Doctor G came to the same conclusion even though he didn't use all the tests which Doctor

living organisms can be explained on the basis of known scientific facts. He also shows how the various configurations seen in the animate world can be duplicated by the study of crystal structures and growth.

The work is stimulating, and is a good approach to the study of the problem which is still far from solved. With the rapid strides that are being made in all branches of chemistry more evidence will be constantly discovered which will tend to explain some of the present still inexplicable manifestations of vital activity.

DAVID M. GRAYZEL

Nursing Through the Years. By Corinne J. Kern. Octavo of 340 pages. New York, E. P. Dutton & Co., 1939. Cloth, \$2.50.

This is a narrative of the experiences in a nurse's life from 1900 until the present day. These reminiscences, while somewhat disjointed, are sympathetically and interestingly told, and are woven together by a thread of biography.

Incidents of the past are somewhat colored by the author's present-day knowledge and experience. It is as though her enthusiasm and pride in the modern developments and practice of medicine and nursing is so great that it overshadows her knowledge of the inadequacies of the past.

The book is full of experiences, perhaps commonplace to a nurse of that period, told in such simple, dramatic, and humanitarian style as to make it interesting and convincing to readers who enjoy stories of this type.

GRACE A. DAY

A Textbook of Obstetrics. With Special Reference to Nursing Care. By Charles B. Reed, M.D., and Bess I. Cooley, R.N. Octavo of 476 pages, illustrated. St. Louis, C. V. Mosby Co., 1939. Cloth, \$3.00.

This is a work which tries to put, in concise and uncomplicated form, the present-day attitude toward obstetrics as an art and a science. It describes the fundamentals of nursing in this branch of medicine, prepares the nurse to appreciate what the doctor is aiming to accomplish, and enables her to furnish practical assistance in routine procedures and be prepared for emergencies.

The important subject of prenatal care is thoroughly covered in four well-written chapters. The nurse plays an important role at this time, by her tact and sympathy, she gives the patient as much hope and confidence as her medical adviser.

The format is pleasing, the type easily read.

FRANCIS B. DOYLE

Heart Patients. Their Study and Care. By S. Calvin Smith, M.D. Octavo of 166 pages. Philadelphia, Lea & Febiger, 1939. Cloth, \$2.00.

Dr. Smith designs this small volume so that the general practitioner can quickly and concisely review the present status of cardiac disorders. He presents the various phases of heart disease briefly and simply. Much that the book contains is sound, but many statements do not conform to the present concepts in the field. It is questionable, from some of the views presented, whether the book has fulfilled its purpose

in being absolutely up-to-date. It is more a summary of the author's own views.

J. HAMILTON CRAWFORD

Roentgen Diagnosis of the Extremities and Spine. By Albert B. Ferguson, M.D. Volume 17 of a series of monographic atlases of the "Annals of Roentgenology." Quarto of 435 pages, illustrated. New York, Paul B. Hoeber, Inc., 1939. Cloth, \$12.00.

Here at last is a volume for roentgenologists. Dr. Ferguson sounds the basic facts of film interpretation of bone and joint pathology.

There are some new terms to learn, but they save time in describing pathologic conditions. Starting with the various changes in form of calcareous matter in the different elements of bone and soft tissue, the book covers the interpretation of fractures, infections, malignancy, bone formation, arthropathies, and finishes with an analysis of spinal curvatures.

When we diagnose films from past experience, we at times do not realize how we arrive at our conclusions. Dr. Ferguson has analyzed the shadows of these normal and pathologic conditions to show how to approach the task in a scientific way. The ample illustrations are equal to the best ever copied, and each one has a story and diagnosis with the opportunity to see case history at the end of the chapter. The index makes it simple for the roentgenologist who is familiar with the basic facts, to seek a particular reference and to obtain with dispatch the wealth of information that this text contains.

GEORGE W. CRAMP

Midwifery. By Ten Teachers. Under the direction of Clifford White, M.D. Edited by Sir Comyns Berkeley, Clifford White, and Frank Cook. Sixth edition. Octavo of 676 pages, illustrated. Baltimore, William Wood & Co., 1938. Cloth, \$6.00.

This book first appeared more than twenty years ago. The present volume is the sixth edition. It is primarily a text on obstetrics produced for students by the combined contributions of ten teachers of obstetrics in various London Medical Schools.

It is well and abundantly illustrated. The foundations of obstetrics are clearly and concisely presented in its 600 odd pages. The viewpoint is naturally English. Chloroform is recommended for the induction of general anesthesia during labor and also in eclampsia. The work is replete with statements of good common sense. For example, in the consideration of diet, antenatal, there is a discussion of the present-day tendency to lay great stress upon the special need for calcium, phosphorus, iron, and vitamins. The writer states, "Their administration is at least harmless, it is probably beneficial, and it is certainly fashionable."

The attitude toward cesarean section is conservative. The lower segment operation is described in detail, the transverse incision in the uterus is the preferred type of procedure.

The work is an excellent textbook for students preparing for examination. It will undoubtedly prove useful to many who have passed beyond the stage of examinations.

Books

Books for review should be sent to the Book Review Department at 1313 Bedford Avenue Brooklyn, N Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers.

REVIEWED

Tumors of the Skin Benign and Malignant. By Joseph Jordan Eller, M D. Octavo of 607 pages. Illustrated. Philadelphia, Lea & Febiger, 1939. Cloth, \$10.

Here is a book which should find a place in the library of every surgeon as well as dermatologist. It would also be very valuable to the general practitioner, since it is, without question, a complete manual of information and procedure written by one whose study of the subject and wide clinical experience extending over many years insures its value and position as an authoritative work. In a single volume, splendidly illustrated with over 400 photographs and diagrams, Dr Eller has brought together the best thought of the present day and the fullest information concerning diagnosis and treatment with radium and x-rays, or whatever surgical procedure has proved superior in the treatment of the benign and malignant lesions of the skin. The chapter on the treatment of carcinomas is most comprehensive and discusses the several methods of therapy which may be used with diagrammatic example of tumors of various types, sizes, shapes, and locations showing very graphically the most advantageous arrangement of the radium applicators used. Precancerous lesions are well described and special emphasis is placed on the recognition and management of early malignant new growths.

One of the most valuable chapters is devoted to cutaneous surgery and plastic repair of skin tumors. The illustrations and diagrams elucidating the various procedures in surgical technique and skin grafting greatly enhance the value of the book.

An extensive appendix contains practical data on radiation physics and biology, including dosage tables and charts which aid in determining the proper procedure and the dose to be employed in the treatment of tumors of the skin.

Dr Eller has dedicated his book to his "friend and mentor," and the master of us all, Dr James Ewing.

NATHAN THOMAS BEERS

Medicine of the Ear Edmund P Fowler, Jr, M D, Editor. Quarto of 590 pages, illustrated. New York, Thomas Nelson & Sons, 1939. Cloth, \$12.

This comprehensive work on the medical aspects of ear disease is a welcome variation from the usual type of otologic textbook. Compiled by a distinguished group of specialists, it makes a fine, ready reference work. The looseleaf arrangement provides for additions from time to time.

The general standard of this book is high, the chapters on physiology and pathology deserve special mention.

The editor and his publishers are to be congratulated for having given us a new type of

text and reference work. The paper, print, and general arrangement are unusually good. This volume should be placed on the list of "musts" for those interested in the subject.

M C MYERSON

The Wisdom of the Body By Walter B Cannon, M D. Revised and enlarged edition. Octavo of 333 pages, illustrated. New York, W W Norton & Co, 1939. Cloth, \$3 50.

This volume discusses the relation of the autonomic nervous system to the self regulation of physiological processes. The word, homeostasis, is used to denote the stability of the body, that is, the coordinated physiologic processes which maintain most of the steady states in the organism. In the chapter on the Fluid Matrix, the blood and lymph are studied. Chapters on the constancy of the water and salt content of the blood, and chapters on the homeostasis of the blood sugar, proteins, fats, and calcium follow.

In discussing the constancy of body temperature, the thyroid gland is stated to be the most influential organ, the pituitary and adrenal cortex also being factors. Causes of heat production and heat loss are explained. This edition has a new chapter on The Aging of Homeostatic Mechanisms. Reduced rate of heat production as the individual grows older is found and also a lessened ability to adapt to external heat, especially in people who are fat. With advancing years there is also an impaired ability to use and store glucose and to maintain the acid base balance of the blood.

The account is based upon a series of fifty three publications from the physiologic laboratory of Harvard University with many other references.

WILLIAM E McCOLLUM

Life's Beginning on the Earth By R. Beutner, M D. Octavo of 222 pages, illustrated. Baltimore, Williams & Wilkins Co, 1938. Cloth, \$3 00.

The question of the origin of life on this planet and its evolution through many stages to its highest culmination in man has always been a subject for speculation by philosophers and scientists. Some claim that life began on this earth while others believe with Arrhenius that life was brought to this earth from some other planet.

The author, himself a keen student of chemistry, set for himself the task of showing how chemistry can account for the beginning of life on this earth without the need of importing living cells from other planets, particularly if millions of years are allowed for the process to develop. By carefully chosen analogies gleaned from the chemical and physical sciences, Dr Beutner shows how all the known forces operating in

living organisms can be explained on the basis of known scientific facts. He also shows how the various configurations seen in the animate world can be duplicated by the study of crystal structures and growth.

The work is stimulating, and is a good approach to the study of the problem which is still far from solved. With the rapid strides that are being made in all branches of chemistry more evidence will be constantly discovered which will tend to explain some of the present still inexplicable manifestations of vital activity.

NEW YORK STATE JOURNAL *of* MEDICINE

Copyright 1940 by the Medical Society of the State of New York

VOLUME 40

FEBRUARY 15, 1940

NUMBER 4

Editorial

A New State Journal

The *North Carolina Medical Journal*, whose first issue appeared in January, promises to make a distinguished contribution to medical journalism. Its attractive format shows a thorough understanding of the technical aspects of magazine-making. More important, its contents reveal a keen awareness of the functions and responsibilities of a state medical journal.

It is not enough for a state journal to act as a medium for the dissemination of scientific papers. That is part of its function, and an important part, but by no means all.

A state medical journal must educate in the broadest sense of the word. It must educate by a discriminating selection of the scientific articles it publishes. It must educate by a constant broadening of medicosocial consciousness in the profession.

The *North Carolina Medical Journal* apparently intends to do both. Its first issue contains a number of superior scientific articles. Its leading article, "The Doctor and Socialized Medicine," by J. Buren Sidbury, M.D., furnishes an excellent analysis of one of the leading medicosocial problems of our times.

The medical profession in North Carolina is apparently cognizant of the need for state intervention in certain aspects of medical care. It acknowledges the success governmental medical activities have had *within their legitimate sphere*. It does not, however, accept the thesis that the provision of general medical care to persons able to pay for such service comes within the legitimate sphere of state medical aid.

As Dr. Sidbury points out, political control of medicine lowers quality and increases costs. Where compulsory insurance is in force, preventive medicine has lagged and malingering and hypochondria increased. Mutual mistrust impairs the relationship between patient and physician, inhibiting intimate revelations on the

Rule No 30 steers a middle course between the extremes of unrestricted and no refills It is a common-sense remedy for an abuse that has reached serious proportions, threatening to create widespread addiction to a potentially dangerous group of drugs

Urolithiasis from Sulfapyridine

The dramatic action of sulfapyridine on the course of pneumonia is in itself an outstanding tribute to chemotherapy However, during the short time that this drug has been in extensive use, an increasing number of dangerous sequelae have been reported in the literature which support clinically the experimental work of Antopol and Robinson¹ and of Gross, Cooper, and Lewis² The former noted the formation of urinary concretions in various portions of the urinary tract of rats, rabbits, and monkeys following the administration of the drug The latter, working on the same therapy for pneumonia, found that over 60 per cent of their animals developed calculi, accompanied by varying degrees of obstruction, hematuria, pyelonephritis, and a high nitrogen content in the blood Pathologically, there were noted albuminous degeneration of the tubular epithelium and dilatation of the ureters and of the renal pelvis The chemical composition of the deposits was found to be acetyl-sulfapyridine, and the calculi varied in color from a grayish white to a pale yellow

Keen,³ in reporting 2 cases of sulfapyridine urolithiasis, draws attention to the aspects that this problem presents in humans "For a pneumonia patient to recover overnight, as it were, and then to be precipitated into an acute abdominal syndrome is an unpleasant aftermath for the patient as well as his physician" Acute renal obstruction, red blood cells and casts in the urine, and severe attacks of lumbar pain speak for caution in the use of this drug lest these concretions form the nucleus for a permanent stone Keen feels that the marked dehydration present in pneumonia coupled with the limited solubility of sulfapyridine may be the responsible factors in the production of calculi

Complications of such gravity following the use of any drug war-

³ Keen M R. New York State J Med. 40 83 (Jan. 15) 1940

former's part For want of time and personal interest, diagnostic methods become superficial and treatment mechanical Graduate medical education is neglected and the standards of professional service gradually fall

Where the low-income classes have been without facilities for medical care or have had access to only the lowest forms of contract practice, compulsory sickness insurance *may* represent an improvement In this country, however, with widespread facilities for medical care and a high order of personalized service available to most of the population, the sort of treatment obtainable under obligatory insurance would be a distinct retrogression Today there is less reason than ever for adopting this method since organized medicine is sponsoring plans for the extension of "quality" medical care to all classes

Dr Sidbury's article proposes concrete remedies for concrete ills He accepts the principle of federal financial aid to provide medical care for the underprivileged but defines the conditions under which such aid is acceptable and produces the best results At the same time he debunks much of the propaganda for state medicine If his article reflects the policy of the *North Carolina Medical Journal*, this newcomer seems destined to assume an important place among state medical publications

Control of Sedatives

Rule No 30 in the new State Sanitary Code places a necessary curb on over-the-counter sales of hypnotic and somnifacient drugs Heretofore many such drugs have been available to the public without a physician's prescription and old prescriptions could be refilled without reference to the issuer's needs As a result, there has developed an excessive reliance on sedatives and somnifacients, almost rivaling the prevalent abuse of laxatives

The new regulations put an end to indiscriminate over-the-counter sales without preventing reasonable lay access to these drugs Rule No 30 provides as follows

"No hypnotic or somnifacient drug intended for internal use shall be sold at retail or dispensed to any person except upon the written prescription of a physician, a dentist or a veterinarian, and the prescription shall remain on file in the pharmacy where compounded Such prescription shall not be refilled if it bears indication by the physician, the dentist or the veterinarian that it is not to be refilled "

The last sentence answers the objection of those who argue that a patient should not be obliged to visit his physician every time he desires to renew a prescription which is safe and desirable for him

insect and animal carrier of disease still exist " Shall we will this Earth to them as their own or shall we, as physicians, continue to aid in preserving it for humans so that *Future*, as defined in the lexicons, will really mean something to our coming generations!

Current Comment

"How good it is that there is still light and peace and hope in the hearts of men somewhere in this trembling world! How good that here among us, the State will apparently spare us yet a little while to walk as men, to speak gently and to save our passions for the tasks of devotion and of love.

"But lest the lamps of freedom, of tolerance, of human kindness be extinguished here, lest the dignity of man give way even on this young soil to the dark terror of the brute that lurks in hungry masses, we must be alert The New Year will be a happy one only as we count our true blessings and join hands to shield the fragile flames within those lamps from the cold winds that blow about us this January 1940"—Greeting from the January issue of the *Westchester Medical Bulletin*

"I don't think these tactics will do any good There is no way of fooling the American Medical Association I think the Senator's bill was drafted largely to ensnare the doctors"—Abraham Epstein, Executive Secretary, American Association for Social Security, testifying before the Senate Committee on Labor and discussing the Wagner National Health Bill

"The medical profession in solid usefulness has far outstripped the legal profession I used to glory in the legal profession But it is a sad fact that that wonderful profession that has in its tradition a host of great men—that great profession—by some subtle influence is steadily deteriorating Law is not a science now

And let me speak a word of warning to you Very much the same influences that strike at the legal profession are be-

ginning to look at you, at socialized medicine, regimentation of you doctors is imminent. Before you know it that freedom you glory in will be suddenly swept away and you will be regimented into a mere body of base practitioners"—Judge Stewart, of Pittsburgh, quoted in the *Easton (Pa.) Express* recently

"In contrast with the *revolutionary* proposals of the Federal officials is the *evolutionary* platform of the American Medical Association " "The well-rounded practitioner is both an *introvert* with a confidence in his own ability, in his private practice, and an *extrovert* in his relations with his fellow practitioners and the public generally"—Two sound comments from the January issue of the *Journal of the Medical Society of New Jersey*

"The years that have vanished into oblivion, and are dead, and the days of our own, so widely divergent in time and space, differ little. The past had its quacks and we have ours now For duodenal ulcer a magnesium sulfate 'mineral water', for gynecological affliction, be it cervicitis, perineal tears, retroversion, neoplasm—benign or malignant, just take Lady Abigail's medicine, and for fatigue, for nervous exhaustion, in fact for constitutional vagotonia, ah, we have it! A cigarette, but only of a certain kind Another make and you're ruined Brazenly and openly, speaking to millions through radio and newspapers, fake nostrums are advocated for colds and coughs, for weakness Weakness, one of the signs of cancer, of tuberculosis, of pernicious anemia. How many graves do these swindlers dig a year?"—Plain speaking in the *Roche Review*

rant serious consideration. There comes to mind the glowing reports of the efficacy of dinitrophenol in obesity and the wave of cataracts that followed its use. Does it not seem advisable to advocate restraint in the use of sulfapyridine to such cases as do not respond to other proved forms of treatment? Is it advisable that the expectation of the "crisis" be shortened from seven days to one, and then turn a medically sick patient into a potential surgical risk?

Despite the enormity of this problem it takes self-control, brined in stoicism to refrain from commenting facetiously upon the currently popular conception that adequate medical care can be obtained only by the collaboration of several specialists in diverse fields on a given case. Who would have thought that the time would come when a urologist, cystoscope in hand, becomes a necessary adjunct to the *proper* management of "a guy dat's sick wid pneumonia?"

Doctors and War

The war abroad grieves us deeply. That problems, no matter what their nature may be, cannot be settled amicably over a conference table seems incredible to minds that function maturely. To us physicians, whose souls are devoted to the conquest of those minor forms of life which daily threaten our existence—bacteria, molds, vegetable and animal parasites, and the so-called viruses, this wanton destruction of men by men appears to be a concerted effort of humanity to relinquish our planet to the progeny of the *snake* that enticed Eve.

We have mastered the immediate problems of the sicknesses which are peculiar to mass concentrations of human beings from all walks of life. Typhoid fever, diphtheria, smallpox, and those diseases innate to war, such as tetanus and gas gangrene, can be controlled to an extent that will give us a minimum in both morbidity and mortality. Trench mouth and trench fever can be remedied satisfactorily. Plastic surgery has advanced to a stage where the most disfiguring wound can be repaired so that the injured may again resume his former status in civil life.

But something is left for which even we physicians have as yet no solution—the postwar epidemic. Those of us who remember the tragedy and horror of the "Spanish Flu" epidemic, during the years 1918 to 1921, which followed immediately upon the termination of the last World War, are alert to the possible epidemic diseases which the current war will bring in its train. "The louse¹ that spreads typhus fever, the rats concerned with plague, and many another

PRESENT TRENDS IN THE TREATMENT OF PNEUMONIA IN CHILDREN

WILLIAM C EMM, M D , Syracuse, New York

PNEUMONIA is one of the leading causes of death and as such presents a definite health problem to every community. Since its first isolation by Pasteur and Sternberg, and since the pneumococcus was proved to be the cause of pneumonia by Fraenkel, this disease has been the subject of intensive experimental and clinical research. As a result of this research the mortality from pneumonia is gradually being lowered. There are several milestones already passed on our road toward a reduction of mortality. First, the prevention of pneumonia which follows the proper management of upper respiratory infections. Second, the introduction of the oxygen tent in the early twentieth century was the culmination of the work of Thomas Beddoes who founded the Pneumatic Institute for the treatment of diseases by inhalation in 1798, and Waldenburg who revised this plan in 1873 and established a differential type of pneumotherapy. In 1897, a third milestone was passed when Washbourn immunized a horse and used the serum in the treatment of pneumonia. This offered protection against some pneumonias but did not seem to influence others. This is one of the earliest observations of the immunologic differences between strains of pneumococci. It led to the discovery of the importance of distinguishing the various strains comprising the pneumococcus group.

The introduction of a potent type specific serum for each strain isolated was the next logical step. Rabbit serum was discovered while attempting to overcome some of the difficulties encountered in the use of horse serum.

In 1935, Domagk demonstrated a drug known as sulfanilamide. Primarily intended for the treatment of hemolytic

streptococcal infections, this drug was noted to have some effect on certain types of pneumococci. Further investigation of sulfanilamide has led to the discovery of M & B 693, or sulfapyridine in 1938.

The evaluation of each of these methods of treatment, or a combination of these methods must, in the final analysis, be determined on a statistical basis. This is particularly true of pneumonia because the individual case need follow no exact pattern and there is no means by which its future course can be accurately determined.

My report of pneumonia extends over a period of four and a half years, from July, 1934, to February, 1939. It consists of an analysis of 515 consecutive cases of pneumonia in children admitted to the Syracuse Memorial Hospital. Only proven cases of pneumonia (consolidation, rales, bronchial breathing, x-ray or fluoroscopy, postmortem examination) were used for this report.

The majority of the children came from poor homes where the lack of proper food and care resulted in a lowering of the child's resistance to all types of infection. Past histories of repeated upper respiratory infections were frequently elicited. Thus it was not surprising to find that the common cold or some allied form of upper respiratory infection was the leading predisposing cause of these pneumonias. Webster and Hughes (1931) have shown that it is possible to isolate a pure culture of pneumococci from the nasal secretions during some phase of every common cold occurring in a child. Every cold then is a potential case of pneumonia, depending upon the type of pneumococcus in the nasal secretions, its power to invade the body, and the child's resistance to the particular type involved. Congenital

Read at the Annual Meeting of the Medical Society of the State of New York, Syracuse, April 26, 1939

"The National Grange is strongly opposed to socialized medicine. At its annual convention in Peoria, Ill., this organization of 1,000,000 farm people went on record as opposing the fundamentals of the Wagner Health Bill now pending in Congress. Without debate it adopted the following resolution:

"We oppose any form of socialized medicine which would be administered by any branch of government, regardless of the cooperation or interest of those for whom the service was provided. This is not opposition or condemnation of cooperative efforts for providing medical care by the people themselves. The Grange is not opposed to voluntarily cooperative plans for medical care, but it does oppose any plan to make the Federal Government supreme in the field of medical care. It believes, as many others do, that this would result in a meddlesome federal bureaucracy and a lowering of the standards of medicine." And when the matter is given thoughtful consideration only a small percentage of people in any walk of life will look with favor on such

proposals as the Wagner Health Bill'—The St. Louis *Daily Globe-Democrat* of December 3, 1939

" 'Doctors are poor business men.' This statement has often been made, and is a charge that, in my opinion, we will not attempt to palliate or deny, since most of us know that when a physician becomes a good business man he often ceases to be a good medical man"—A statement by Ralph B. Todd, M.D., former president of the Westchester County Medical Society.

"Were all men built to a stock pattern so that they responded to physical agents or bacterial infections in regular fashion according to their peculiar constitution, the practice of medicine would be a simple business. All men, however, are like contrary women of whom the comedian sang 'You never see two alike any one time and you never see one alike twice'."—*Quincy Medical Bulletin*, recently

Prize Essays

The Merritt H. Cash Prize and the Lucien Howe Prize will be open for competition at the next Annual Meeting of the Medical Society of the State of New York, May 6, 1940.

The Lucien Howe Prize of \$100 will be presented for the best original contribution on some branch of surgery, preferably ophthalmology. The author need not be a member of the Medical Society of the State of New York.

The Merritt H. Cash Prize of \$100 will be given to the author of the best original essay on some medical or surgical subject. Competition is limited to the members of the Medical Society of the State of New York, who at the time of the competition are residents of New York State.

The following conditions must be observed:

Essays shall be typewritten or printed and the only means of identification of the author shall be a motto or other device. The essay shall be accompanied by a sealed envelope having on the outside the same motto or device and containing the name and address of the writer.

If the committee considers that no essay or contribution is worthy of the prize, it will not be awarded.

All essays must be presented not later than April 1, 1940, and sent to the Chairman of the Committee on Prize Essays of the Medical Society of the State of New York, 2 East 103rd Street, New York City.

EUGENE H. POOL, M.D., Chairman, Committee on Prize Essays

cal mastoiditis occurred in 6.4 per cent of the cases. Next in frequency was empyema in 6.6 per cent of the cases. The complete list of complications is given in Table 3. Recovery from pneumonia without complication of any sort was noted in approximately 60 per cent of the cases in this series. Complications were noticeably fewer in the serum-treated cases and usually, when they occurred they were present before the serum was administered.

There were 79 deaths in this series, a mortality of 15.4 per cent. This is compared with other series of pneumonia recently published (Table 4). The mortality of routinely treated cases was 15.6 per cent. The mortality of serum-treated cases was 5 per cent. There were 4 deaths in the 8 cases of tuberculous pneumonias. An analysis of the deaths shows that 32 cases were complicated by some other pathology in addition to the pneumonia. In Table 5 further analysis shows that 85 per cent of the deaths, or 68 cases, occurred in children 2 years of age or younger. One is impressed by the large number of cases which were not typed. Typing was not an established procedure during the first two years. Omission of typing during the last two years was because of the poor condition of the patient, making it impossible to pass a stomach tube. Group X, next in frequency, contains the higher types of pneumonia for which no specific serum was available. Five deaths were noted in types for which serum was available. Two of these received serum. The treatment of the pneumonias was both general and specific. General or routine treatment was given 467 cases in this series.

It consisted of isolation in a pneumonia unit with a permanent nursing staff, adequate fluid intake by mouth supplemented by hypodermoclyses or intravenous solutions, adequate rest, oxygen therapy for labored breathing, and the symptomatic relief of cyanosis. The majority of the cases treated in this manner were classified as Type X or the higher types for which there is no specific treatment generally available.

Specific serum therapy was used in 40 cases. They included those types for which serum is supplied by the state laboratory, namely Types 1 and 2. In Types 5 and 7 horse serum and rabbit serum were also used. The number of cases treated with serum is, as yet, too few to offer a suitable comparison with

FIG 1

heart disease of all types, the contagious diseases, measles, whooping cough, and chickenpox, diarrhea specific and non-specific, asthma, and eczema were predisposing factors in this series. Three cases followed tonsillectomy and 1 followed an extensive burn.

The majority of the cases were treated during the winter and early spring months (Fig 1). In the first two years, single waves of increasing incidence occurred in the early spring months. The last two years were marked by two waves occurring in midwinter and early spring. The distribution of cases according to type and various age groups is shown in Table 1. The cases are nearly evenly divided between lobar and bronchopneumonia. Most of the pneumonias occurred in children 2 years of age or under and were predominantly bronchopneumonia. The lobar pneumonias were more prevalent in the older age groups. There were 8 cases of tuberculous pneumonia.

Sputum typing should be a routine procedure in all cases of pneumonia regardless of age. In small children there are several methods which may be used to collect a satisfactory specimen. If the child is old enough to cooperate, he may be able to cough and raise a representative bit of pulmonary secretion. Simple tickling of the throat may aid in bringing up the sputum. A throat swab culture may be used but this is subject to criticism for, while it may produce the causative organism, it may give an organism normally found in the child's throat playing no part in the infection. The easiest and most reliable method is simple aspiration

TABLE 1

Pneumonia	Up to 2 Yrs Age	2-5 Yrs Age	5-15 Yrs Age	Total
Lobar	87	68	99	154
Broncho	190	44	19	253
Tuberculous	4	2	2	8
Total	281	114	120	515

of the stomach contents. The tendency of every child to swallow secretions, particularly those raised during spells of coughing, makes this procedure almost infallible. Failures with this method are most often associated with small amounts of sputum highly diluted with stomach contents, making it difficult to find the pneumococci. Aside from the factor of dilution, the nature of the stomach contents does not affect the procedure of typing. Routine blood culture may at times yield an organism for typing which may be used to confirm the results of sputum typing.

All of the typing in this series was done by the Neufeld method at the City Laboratory, under the supervision of Dr O D Chapman. This method of typing is based on the fact that the capsule of the pneumococcus becomes swollen in the presence of its homologous serum. Very little typing was done the first two years of this survey. Thereafter it was a routine procedure. At that time the laboratory was typing only for Types 1, 2, 3, 5, 7, 8, and 14 with other types designated as Group 4 or X. In the past six months the typing has been extended to include all of the thirty-two known types. The results of our typing are shown in Table 2. Types 1, 5, and 14 were predominant for the series. Types 14, 6, and 3 predominated in the younger age group while Types 1, 5, and 7 were more common in the older age groups. The difficulties encountered in typing often lie in obtaining the type of pneumococcus which is the causative factor. This is illustrated by the following two examples. In the first case, four attempts at typing gave 16 and 17, 18 and 23, 28, 18. The second, on three attempts gave 10-17-15 1-8-14, and then became negative. Interpretation of such results is extremely difficult.

The leading complication was otitis media, occurring in 23.6 per cent. Surgi-

4. The general use of sulfapyridine in the treatment of pneumonia must await further clinical and experimental research

Discussion

Dr A. Wilmot Jacobsen, Buffalo, New York—I have been very much interested in Dr Emm's paper because it has given me opportunity to compare his figures with those of a similar five-year survey which we conducted a year ago at the Children's Hospital of Buffalo. I wish to congratulate Dr Emm on his excellent mortality figures beside which our statistics make a rather poor showing. Our mortality for the five-year period, during which there were 810 cases of pneumonia in the hospital was 30 per cent as compared to his figure of about half this.

But unfortunately for purposes of comparison our series is rather different from Dr Emm's in that there are included in it all children showing autopsy evidence of pneumonia as well as the clinical cases, and since a very high percentage of infants have a terminal pneumonia regardless of the primary cause of death, our mortality figures appear high. One point which our survey brought out very clearly is the necessity of running a coincident control series of cases when attempting to estimate the value of therapy in pneumonia. Our mortality figures for the five years from 1933 to 1938 were successively 40, 33, 32, 29, and 21 per cent. We are unable to account for this progressive decline in mortality because during this period there was no change in our methods of treatment. It shows the fallacy of comparing the statistics of one year with those of another.

For this reason we are now testing the value of sulfapyridine by using it on alternate admissions. We were fortunate in receiving a complimentary supply of this drug from the start and thus far we have treated 24 cases of pneumonia with a similar number of controls. This is a very small series but our impressions might be of interest.

The patients in the sulfapyridine group almost invariably showed a drop in temperature within twelve to thirty-six hours after commencing the drug. Thus made the duration of the disease two days shorter than in the control group. Coinci-

dent with the drop there was also clinical improvement. Several children vomited repeatedly for twelve to twenty-four hours but this ceased although administration of the drug was being continued. In this small series we saw no other toxic effect except mild cyanosis. In short our series would fit perfectly with the beautifully controlled group of cases recently reported from Cincinnati in the *Journal of the American Medical Association* which you have all doubtless read.

In 2 of our cases, sulfapyridine seemed to exert no effect, and a recent paper in the *Lancet* by McLean, Rogers, and Flemming offers an explanation for this. They report a method for testing *in vitro* the sensitivity of a strain of bacteria to sulfapyridine, and by this method pneumococci have been found to vary enormously in their sensitivity to the drug and this variation is not associated with the type of pneumococcus but with the individual strain. But what was most interesting, as well as surprising, was the discovery that a single dose of pneumococcus vaccine given to mice or rabbits profoundly affects the course of an experimental infection in these animals when treated with sulfapyridine. A strong case is made out for the combined use of vaccine and sulfapyridine in pneumonia in man.

It has also been shown that pneumococci in infected animals readily establish a tolerance or fastness to the drug, and this experimental evidence should be made use of in treating patients by giving large initial doses so that the destruction of the bacteria may be complete before they have established tolerance to the drug.

Perhaps the best test we have of the effect of a drug on the pneumococcus is a case of pneumococcus meningitis, which is to all intents and purposes a human test tube in which the effect of a definite concentration of the drug can be determined by studying the spinal fluid. It cannot be an accident that the last two examples of this disease that I have seen are the only two that were treated with sulfapyridine and are also the only two who got well. In one of these the spinal fluid was promptly rendered sterile and while the concentration of the drug in the spinal fluid varied from 6 to 8 mg per cent it remained sterile. When the concentration fell to $2\frac{1}{2}$ mg per cent there was a recurrence which was promptly cured when increased dosage pushed the level above 6 mg again.

However, in this case enormous doses were given. Ordinarily the concentration of sulfapyridine was between 1.0 and 2.5 mg per cent, which is less than half the concentration we usually find in the blood of children treated with sulfa-

TABLE 5

those treated routinely. The results with serum, however, give some indication of the usefulness of this type of therapy. Serum offers the greatest benefit in the age group of 2 years or under, where 1 out of every 4 cases dies. Unfortunately many of these cases are caused by types of pneumococci for which there is no acceptable serum for general use. However, all cases in this group of a type with available serum should be given the benefit of the serum. In the older age groups in this series the mortality of routinely treated cases was 5 per cent. The use of serum in these older age groups is a debatable question and should be employed in selective cases. A positive blood culture, a severe toxemia, a rapidly spreading pneumonia, or a cardiac condition are factors determining the selective use of serum for this group. Five deaths are noted in types for which serum was available. Two of these, both Type 5, received large doses of serum without result. The 3 cases of Type 1 were seen late in the course of the disease and no serum was given. One apparently recovered from pneumonia only to die suddenly of circulatory failure, acute endocarditis complicated the second, and the third died of empyema.

We have had an opportunity to observe the use of sulfapyridine in several cases of pneumococcal infections in children. I am indebted to Dr. H. Van Zile Hyde for permission to present a part of this work, a detailed report of which will be published at a later date by Dr. Hyde. Sulfapyridine is a white crystalline solid, soluble in water 1-1,000. It is active in relatively small doses and reported to be less toxic than sulfanilamide, although proof of this fact depends upon a longer clinical test of the drug. It is as effective as sulfanilamide against the hemolytic

streptococcus and meningococcus but possesses a greater effectiveness against pneumococcus. Reports so far available show the drug to be most effective against Types 1, 7, and 8, although it offers considerable protection against 2, 3, and 5. Type 1, 3, 14, and 18 infections occurring in children have been given this drug. No calculated dosage was given, the clinical picture determining the dose and the length of time the drug was given. Two untyped pneumonias in premature infants were also treated. The results in these cases were striking, each showing a quick response to the drug with termination of the infection. Two failures have occurred, one a Type 1 meningitis, the other a Type 27 endocarditis. Neither case showed any response to the drug. Vomiting, a slight cyanosis, and an itching of the eyes have been the only untoward signs noted during the administration of the drug. The number of cases is too few to draw any definite conclusions. When added to reports already published it would seem to indicate that sulfapyridine is an effective chemotherapeutic agent in the treatment of pneumonia and may revolutionize the entire treatment of this disease. Only prolonged careful study with accurate and complete clinical reports will answer this question.

Summary

1. A series of pneumonias in children has been reviewed as to incidence, predisposing causes, complications, and methods of treatment.

2. Serum should be employed in all patients 2 years of age or under whenever possible.

3. Serum should be employed in selective cases in older age groups of children.

4 The general use of sulfapyridine in the treatment of pneumonia must await further clinical and experimental research

Discussion

Dr A. Wilmot Jacobsen, Buffalo, New York—I have been very much interested in Dr Emm's paper because it has given me opportunity to compare his figures with those of a similar five-year survey which we conducted a year ago at the Children's Hospital of Buffalo. I wish to congratulate Dr Emm on his excellent mortality figures beside which our statistics make a rather poor showing. Our mortality for the five-year period during which there were 810 cases of pneumonia in the hospital, was 30 per cent as compared to his figure of about half this.

But unfortunately for purposes of comparison our series is rather different from Dr Emm's in that there are included in it all children showing autopsy evidence of pneumonia as well as the clinical cases, and since a very high percentage of infants have a terminal pneumonia regardless of the primary cause of death, our mortality figures appear high. One point which our survey brought out very clearly is the necessity of running a coincident control series of cases when attempting to estimate the value of therapy in pneumonia. Our mortality figures for the five years from 1933 to 1938 were successively 40, 33, 32, 29, and 21 per cent. We are unable to account for this progressive decline in mortality because during this period there was no change in our methods of treatment. It shows the fallacy of comparing the statistics of one year with those of another.

For this reason we are now testing the value of sulfapyridine by using it on alternate admissions. We were fortunate in receiving a complimentary supply of this drug from the start and thus far we have treated 24 cases of pneumonia with a similar number of controls. This is a very small series but our impressions might be of interest.

The patients in the sulfapyridine group almost invariably showed a drop in temperature within twelve to thirty-six hours after commencing the drug. This made the duration of the disease two days shorter than in the control group. Coinci-

dent with the drop there was also clinical improvement. Several children vomited repeatedly for twelve to twenty-four hours but this ceased although administration of the drug was being continued. In this small series we saw no other toxic effect except mild cyanosis. In short our series would fit perfectly with the beautifully controlled group of cases recently reported from Cincinnati in the *Journal of the American Medical Association* which you have all doubtless read.

In 2 of our cases, sulfapyridine seemed to exert no effect, and a recent paper in the *Lancet* by McLean, Rogers, and Flemming offers an explanation for this. They report a method for testing *in vitro* the sensitivity of a strain of bacteria to sulfapyridine, and by this method pneumococci have been found to vary enormously in their sensitivity to the drug, and this variation is not associated with the *type* of pneumococcus but with the individual *strain*. But what was most interesting, as well as surprising, was the discovery that a single dose of pneumococcus vaccine given to mice or rabbits profoundly affects the course of an experimental infection in these animals when treated with sulfapyridine. A strong case is made out for the combined use of vaccine and sulfapyridine in pneumonia in man.

It has also been shown that pneumococci in infected animals readily establish a tolerance or fastness to the drug, and this experimental evidence should be made use of in treating patients by giving large initial doses so that the destruction of the bacteria may be complete before they have established tolerance to the drug.

Perhaps the best test we have of the effect of a drug on the pneumococcus is a case of pneumococcus meningitis, which is to all intents and purposes a human test tube in which the effect of a definite concentration of the drug can be determined by studying the spinal fluid. It cannot be an accident that the last two examples of this disease that I have seen are the only two that were treated with sulfapyridine and are also the only two who got well. In one of these the spinal fluid was promptly rendered sterile and while the concentration of the drug in the spinal fluid varied from 6 to 8 mg per cent it remained sterile. When the concentration fell to $2\frac{1}{2}$ mg per cent there was a recurrence which was promptly cured when increased dosage pushed the level above 6 mg again.

However, in this case enormous doses were given. Ordinarily the concentration of sulfapyridine was between 1.0 and 2.5 mg per cent, which is less than half the concentration we usually find in the blood of children treated with sulfa-

nilamide And yet these much smaller levels seem to be effective in the case of sulfapyridine

The moral of all this is that a new era has dawned in the treatment of pneumonia, and no longer can "rest in bed" alone be considered adequate therapy

Dr Albert D Kaiser, Rochester, New York—The treatment of pneumonia in children has been considerably augmented during the last few years Until a few months ago it appeared that serum therapy would favorably influence the chances of recovery in pneumonia In recent weeks, reports are being published on the use of sulfapyridine in the treatment of pneumonia that seem to be even more optimistic than serum-treated cases It may be some time, however, before it can be stated definitely that serum treatment should be abandoned in favor of chemotherapy

No one familiar with the use of sulfapyridine in the treatment of pneumonia can fail to be impressed by the rapid response to this drug

Reports published thus far agree that the mortality is reduced where the drug is used However, the death rate is not high in children so that further observations must be made before it is certain that sulfapyridine lowers the mortality in pneumonia It seems to be quite certain, however, that the duration of pneumonia is shortened and that the incidence of complications is lessened when this drug is used.

Sulfapyridine promises to be helpful in the type of pneumonia for which a specific serum has not been available, so-called bronchopneumonia, pneumonia following measles and pertussis. The drug should be used in these cases

The administration of sulfapyridine is relatively safe The reactions are usually not severe. The earlier the drug is given the quicker the results This means that a definite diagnosis of pneumonia cannot always be made. If, however, pneumonia can be prevented in some treated cases it is justifiable to use sulfapyridine even when the indications are not absolutely clear

INTENSIVE POSTGRADUATE COURSE IN OPHTHALMOLOGY

The George Washington University School of Medicine, Washington, D C, will have the following as guest lecturers during March 25-30 Dr A Bielschowsky, who will give two lectures daily on Motor Anomalies of the Eye, *illustrated with Case Demonstrations*, Dr Wiley R. Bufington, Vascular Changes in the Ocular Fundus, Dr Grady E Clay, Diseases of the Optic Nerve, Dr Harry S Gradle, Ocular Therapeutics, Dr Daniel B Kirby, The Surgical Treatment of Cataract, Dr Peter Kronfeld, The Ophthalmoscopic Picture of Retinal Detachment and Its Interpretation, Dr Ralph Irving Lloyd, Ocular Syndromes, Dr S Hanford McKee, Allergy in Relation to Ophthalmology, Dr C S O'Brien, Glaucoma, Dr Avery DeHart Prangen, 1 Applied Refraction, 2 Differential Diagnosis of the Phorias, Dr Bernard Samuels, Sympathetic Ophthalmia, Dr Albert C Snell, Industrial Ophthalmology, Dr Edmund B Spaeth, Plastic Surgery of the Eye, Dr Georgiana Dvorak Theobald, Pathology of the Eye, Dr Phillips Thygeson, Conjunctivitis, Dr Robert Von der Heydt, 1 Slitlamp Findings of Trauma to the Eye and Lens, 2 Color Photograph Clinic of Rare and Interesting Fundi and Anterior Eye Conditions, and Scott Sterling, Ophthalmic Lenses

The Staff of the Department of Ophthalmology, the George Washington University School of Medicine will present Dr Wm. Thornwall Davis, lecturing on Treatment of Accommodative Squint, *illustrated by Case Demonstrations*, Dr G Victor Simpson, Neuro-Ophthalmology, Dr Ernest Sheppard, The Ocular Manifestations of Syphilis, Dr E Leonard Goodman, The Surgical Treatment of Glaucoma, Dr Ronald A Cox, The Lacrimal Apparatus, and Commander J C Adams, Medical Corps, U S N, Aviation Ophthalmology

The fee is \$50 (\$15 payable with registration) A Special Practical Course in Ocular Surgery, Pathology, and Orthoptics will be given and will be limited to 25 participants—March 10-23, 1940 (inclusive) The Resident Staff of the Department of Ophthalmology of the George Washington University School of Medicine and the Army Medical Museum will give lectures on 1 Surgery of the Eye on Cadaver and Animal Eyes, 2 Ocular Pathology at the Army Medical Museum with material from the Registry of Ophthalmic Pathology of the American Academy of Ophthalmology and Otolaryngology, and 3 Practical course in the technique of Orthoptic Training

THE USE OF AMPHETAMINE (BENZEDRINE) SULFATE IN ALCOHOLISM WITH AND WITHOUT PSYCHOSIS

EDWARD C. REIFENSTEIN, JR., M.D., and EUGENE DAVIDOFF, M.D.,
Syracuse, New York

(From the Department of Psychiatry, Syracuse University College of Medicine, and from the Syracuse Psychopathic Hospital)

IN JANUARY, 1936, we began an investigation of the stimulating action of amphetamine (benzedrine) sulfate on abnormal mental states characterized by depression or self-absorption. Certain toxic depressive states due to alcohol were included. We observed that the alcoholic cases were among those most favorably affected, and in October, 1936, we reported¹ a beneficial response in 6 of 7 cases with a history of more than moderate alcoholic indulgence.

In May, 1937, we presented² a comparative study of 55 depressed and self-absorbed patients, and stated that the most consistent improvement was obtained in the alcoholic cases. These observations lead us to investigate a series of 28 cases with acute alcoholic psychoses of recent onset. The definite, and, at times, marked acceleration of improvement which was observed in 93 per cent of these patients was recorded in the preliminary report published in May, 1938.³ We also found a more satisfactory response in states of intoxication brought on by alcohol in which no psychosis was demonstrable and in the depressive after-effects of alcoholism. Subsequent comparison with the response of other psychiatric conditions^{4,5} has served to emphasize the relative effectiveness.

In the present communication we have extended our study to a series of over 100 cases of alcoholism with and without psychosis and have compared the results with a comparable series of consecutive cases that did not receive amphetamine sulfate. For purposes of convenience, we have grouped the case material in five subdivisions: (1) acute alcoholic

psychoses, (2) protracted alcoholic psychoses tending toward deterioration, (3) without psychosis acute intoxication, (4) without psychosis chronic alcoholism involving addiction, and (5) alcoholic states complicating other mental illness.

Method

As soon as a patient in an alcoholic state was admitted to the hospital, he was subjected to a thorough physical and mental examination and was given amphetamine sulfate unless the medication was contraindicated by reason of severe hypertension or cardiac disease. The dosage was usually 20 to 30 mg. daily as a single dose, and the drug was administered orally, intravenously, or at times by both routes. Unpleasant and untoward reactions were negligible for the most part. All other medications and procedures were omitted deliberately. The physiologic and the psychologic status of the patient was observed at frequent intervals according to methods previously reported.^{2,6,7,8,9} After an interval of observation, the patient was presented at a staff conference and an official diagnosis was established following the classification of the American Psychiatric Association. The disposition of the patient was then determined. In most instances, amphetamine sulfate was continued throughout the residence of the patient in the hospital. Upon discharge, whenever possible, the patient was referred to the outpatient clinic to continue medication.

In an estimation of the influence of the drug in these cases, consideration was given to (a) the opinion of the staff members who were unaware of the medica-

nilamide And yet these much smaller levels seem to be effective in the case of sulfapyridine

The moral of all this is that a new era has dawned in the treatment of pneumonia, and no longer can "rest in bed" alone be considered adequate therapy

Dr Albert D Kaiser, *Rochester, New York*—The treatment of pneumonia in children has been considerably augmented during the last few years Until a few months ago it appeared that serum therapy would favorably influence the chances of recovery in pneumonia In recent weeks, reports are being published on the use of sulfapyridine in the treatment of pneumonia that seem to be even more optimistic than serum-treated cases It may be some time, however, before it can be stated definitely that serum treatment should be abandoned in favor of chemotherapy

to consider him psychotic because of the rapid improvement of the mental state.

It is likely that some cases would have been classified as pathologic intoxication rather than as without psychosis had they not received amphetamine sulfate. Statistically, this seems apparent in Table 3. The percentage of cases diagnosed as pathologic intoxication decreased from 20 per cent in the control period to 15 per cent in the amphetamine period at the same time that the cases classified as without psychosis increased from 26 to 36 per cent.

Favorable results were observed also in the cases of delirium tremens. This is indicated in Fig 1. The drug was most effective in cases of recent onset. However, greater care was necessary in the selection of patients for treatment because of the organic alterations that accompanied the more protracted cases. The frequent occurrence of complicating physical conditions such as pneumonia or vitamin deficiency necessitated additional caution. For these reasons our amphetamine treated cases represent a selected group. When compared with a similarly selected control group of consecutive admissions, the length of time for recovery in the treated cases was found to be decreased by more than half. In considering these results, recognition must be given to the fact that certain of the cases received other medication such as paraldehyde, barbiturates, and even morphine, prior to admission, and that a synergistic or antagonistic action of these

TABLE 3—VARIATIONS OF DIAGNOSTIC GROUPINGS IN TREATED AND CONTROL CASES

drugs with amphetamine is conceivable in these cases.⁹

The results of treatment with amphetamine sulfate in the patients with acute hallucinosis, while moderately favorable, were not as striking as those of the two previous diagnostic groups. At the same time a comparison with a similar control group of consecutive admissions revealed that 3 of 8 control patients were committed while only 1 of 8 amphetamine patients required further institutionalization. The less favorable response in acute hallucinosis is partially explained in another communication by one of us (Davidoff¹⁰) on the basis of the inadequate personality frequently encountered in this group.

2 Protracted Alcoholic Psychoses Tending Toward Deterioration—The results of the use of amphetamine sulfate in patients with Korsakow's psychosis, while less impressive than those of the acute alcoholic psychoses, were fairly satisfactory, particularly when compared with the control cases. In the latter group of 7 consecutive patients only 1

tion employed in a given case, (b) the response as compared with control cases, (c) the rapidity of dissipation of the psychotic state, (d) the length of time to transfer to a convalescent ward, (e) the length of hospital residence, and (f) the final disposition of the patient (committed or discharged)

Results

1 Acute Alcoholic Psychoses—In this group we include cases diagnosed as pathologic intoxication, delirium tremens, and acute hallucinosis. The most striking difference between the 35 amphetamine treated cases and the 35 control cases was observed in the rapidity with which the psychotic symptoms disappeared in those patients receiving the drug. These results are indicated in Table 1. However, the percentage of recoveries was moderately increased by the use of amphetamine sulfate, for 94 per cent of the treated cases recovered, as contrasted with 86 per cent of the control cases. Only 2 amphetamine patients were committed, while 5 control cases required additional institutionalization.

Of the acute alcoholic psychoses the

Amphetamine cases	7	5	10.6	2

cases of pathologic intoxication responded best. When compared with control cases the average length of time for recovery was diminished by half (Table 2). Those patients receiving amphetamine sulfate were transferred more quickly to a convalescent ward, and in spite of the fact that we were interested particularly in these cases, they tended to stay in the hospital for a shorter period of time. It was not uncommon for all evidences of psychosis to disappear in twenty-four to forty-eight hours, indeed, physicians who had not seen the patient at the time of admission, frequently were reluctant

fied as without psychosis chronic alcoholism involving addiction. We are not discussing the more-than-occasional social drinkers, but chronic imbibers who have developed sufficiently abnormal reaction patterns while drinking to necessitate admission to a mental hospital to determine whether or not they are psychotic. In the hospital these patients, although not considered psychotic, exhibited frequently depressive after-effects of continuous daily imbibing. On these symptoms amphetamine sulfate exerted the usual ameliorative effect.

An effort was made to uncover and adjust the fundamental problems underlying the addiction in all of the alcoholics during their stay in the hospital, utilizing the enforced abstinence of institutionalization, the stimulating action of amphetamine sulfate, and psychotherapy. As far as possible all patients were urged strongly to attend the outpatient clinic following discharge in order to continue medication and the psychotherapeutic endeavors of the physician. However, a discouragingly small number of patients reported for more than one visit, although almost all had expressed their earnest desire to receive assistance in overcoming the habit. The unreliability of the chronic alcoholic in this respect is notorious. The obstacles to clinic treatment introduced by the overprotective attitudes, the falsified reports, and the personal drinking habits of marital partners or other relatives, are too well known to need further comment. Those patients who did report were for the most part sporadic in their attendance, and soon were bored by the therapeutic program. The personality factors contributing to this behavior have been pointed out elsewhere by one of us (Davidoff¹⁰).

Of 30 patients who attended the clinic with some regularity, temporary improvement in regard to addiction has been observed in only 3 of the recent cases. All patients who have been followed more than three months have had at least one relapse. Most of them sooner or later discontinued the medication of their own accord or abused its use. Psychotherapy,

employed during the period when the patients were attending the clinic, were taking amphetamine sulfate, and were presumably abstinent, appeared to be no more effective than during the spontaneous intervals of sobriety which occurred in the control cases or during the enforced abstinence of institutionalization when no medication was administered. We have not been able to observe any deterrent effect on the alcoholic habits of these chronic drinkers from the continuous or sporadic use of amphetamine sulfate. Indeed, the opposite seems to occur at times. Some patients, placing false reliance on the knowledge that the distressing after-effects are dissipated quickly by the drug, imbibe more freely and then resort to the ill-advised and dangerous procedure of self-medication. This undesirable practice has extended to social drinkers.

The continued unsatisfactory response of chronic alcoholic addicts to amphetamine sulfate, which has been evident consistently since the inception of the investigations, serves to emphasize our statement in a previous communication⁴ "that successful treatment of chronic alcoholism itself requires hospitalization in an institution set aside for this purpose. Only by thus restricting the use of amphetamine sulfate can physicians be assured of adequate supervision, which will minimize the dangers of unfavorable events and prevent the abuse of this useful drug."

In January, 1939, Bloomberg¹² reported 21 cases of chronic alcoholism treated with amphetamine sulfate in office and clinic practice. Eight of his cases discontinued drinking for periods varying from two weeks to thirteen months. Four cases were considered total failures, although the others exhibited only moderate improvement. He concluded that the drug is of great value in the treatment of chronic alcoholism, in that it may permit a sufficient interval of sobriety for the employment of psychotherapeutic procedures. As is evident from the previous discussion, we cannot share this opinion because our results in

showed any degree of improvement, 5 required commitment, and 1 died. In the amphetamine series only 2 required further institutionalization. The tendency toward deterioration, the complicating physical conditions and vitamin deficiencies, and the preadmission medication presented obstacles for satisfactory treatment similar to those encountered in the delirium tremens group. The statistical data in Table 3 revealed that the percentage of cases diagnosed as Korsakow's psychosis decreased from 10.8 per cent in the control period to 2.3 per cent in the amphetamine period at the same time that the cases classified as delirium tremens increased from 14.9 to 19.3 per cent. This seems to indicate an aborting effect of amphetamine sulfate on the symptoms of Korsakow's psychosis (subacute type) with a resultant classification as delirium tremens.

In the other more severe, deteriorating types of alcoholic psychoses where personality alterations and organic sensorial defects were present and progressive, amphetamine sulfate appeared to be without value. In the series of control and amphetamine patients, almost all were sooner or later committed regardless of whether amphetamine sulfate had been administered.

3 Without Psychosis Acute Intoxication—We have been impressed repeatedly with the effectiveness of amphetamine sulfate in the acute phases of alcoholic intoxication. Frequently, boisterous, excited, hyperactive, surly, and irritable individuals are quieted by the drug, a few fall asleep after the medication. Beginning tremor in these patients is aborted. Occasionally, however, the drug appears to increase the excitement or the tremulousness. The incoherence and incoordination characteristic of the more profound stages of inebriation is replaced rapidly by a more sober coordinate state. Persons who have imbibed sufficiently to become stuporous have been aroused within thirty minutes following the intravenous injection of 20 to 30 mg of amphetamine sulfate. The drug has rendered depressed, sullen, and asocial

intoxicated individuals more cheerful and adaptable. Certain of our chronic alcoholics have developed the habit of taking amphetamine sulfate in preparation for periodic excessive indulgence. They claim that they are able to consume larger quantities of alcohol without the appearance of unpleasant symptoms. For the same reason, other patients carry the drug in tablet form with them and take it during or subsequent to an alcoholic spree. Some persons obtain the same results by excessive use of the amphetamine inhaler. Patients receiving amphetamine sulfate daily for chronic alcoholism at times severely overdose themselves while too intoxicated to be responsible and to remember how many tablets they have taken. Others occasionally overdose themselves in attempting to ingest an amount of amphetamine sulfate commensurate with the quantities of alcohol consumed.

Following any period of excessive indulgence there appears, within some hours, the characteristic physiologic and psychologic after-effects and withdrawal symptoms. In persons who have received amphetamine sulfate during the acute stages of intoxication these symptoms are aborted or mild. In other individuals who are not thus medicated previously, these disturbing symptoms can be dissipated quickly within a few hours by oral doses of 10 to 20 mg of the drug. Wilbur, MacLean, and Allen¹¹ have made similar observations. These after-effects of an acute alcoholic episode in chronic alcoholic individuals can be similarly alleviated without altering the habitual tendency toward inebriation.

4 Without Psychosis Chronic Alcoholism Involving Addiction—A review of the alcoholic individuals admitted to the hospital over a period of several years and diagnosed as without psychosis alcoholism revealed that a number of these persons were readmitted subsequently with deteriorating psychoses. In these cases amphetamine sulfate had no beneficial or deterrent effect. These cases further indicate the type of patients we are including in the group classi-

men If it is not neglected, it is often treated about the same way in which the friends of the patient would treat him, which is to get him off the particular bout rather than with definite rehabilitation in view

Alcoholism in any form is a medical problem with many psychologic aspects Any of us who have had experience know that we cannot expect any medicine to change a fundamental personality defect We see that in this series of cases amphetamine has shortened the length of time that the alcoholic has been sick Its application in private practice does present many difficult problems Even the person who comes to one's office begging for help to cure his alcohol addiction finds some excuse after a week or so not to keep his appointment, and you next hear that he is being treated for his alcoholism by someone else.

The little success that I have had in treating alcoholics, and it is very little, seems to me to hinge largely upon development of the patient's personality, so that social satisfactions are available to him, and upon the development of the ambition to be a teetotaler Whenever the ambition to be a moderate drinker persists, the alcoholism continues

Dr Robert J Stein, *Canandaigua New York*—There are several reasons why Dr Reifenstein and Dr Davidoff are to be commended on the excellent paper we have heard today First, they have shown us fairly conclusively the definite value of benzedrine sulfate in acute phases of alcoholism with and without psychosis Secondly, their paper includes, more or less, the results of a scholarly investigation which was first initiated in 1936 In spite of many early encouraging results, the authors did not let enthusiasm interfere with their making a careful study of the value of this drug Proceeding cautiously, they made a comprehensive survey of the pharmacologic physiology of benzedrine sulfate, and subsequent clinical investigations have all been adequately controlled Thirdly, their unsatisfactory results obtained in treating chronic alcoholism emphasize the seriousness that confronts the medical profession in dealing with this problem

On the other hand success in treating acute alcoholism, and the study of benzedrine sulfate's physiologic properties, may well serve to stimulate additional research by considering the following facts Our present accepted treatment of the chronic alcoholic is based on a resolving of psychogenic factors that may account for the need of alcohol followed by a re-education and rehabilitation of the individual I believe this

treatment is undoubtedly directed toward the reason why an individual may find an "escape" with alcohol, but that we have lost sight of what has happened to him biologically so that he becomes an alcoholic By this I mean, supposing the above accepted treatment is carried out successfully, the chronic alcoholic can never again use alcohol in moderation, and a cure is based wholly on the ability of an individual to live his life without alcohol being included in his diet In short, because attempts to discover definite biochemical or physiologic changes in chronic alcoholism have been unsatisfactory, the individual is not being treated as a psychobiologic entity

With the information we already have concerning the physiologic changes in alcoholism, how can we then correlate some of the findings presented to us today by Dr Reifenstein? Studies have shown that the toxicity of alcohol is influenced inversely by the concentration of the sugar in the blood Clinically we have noticed improvement in "hang-over" symptoms after a patient has ingested sugar We have discovered that in delirium tremens there is a lowered oxygen uptake, reduction in blood chlorides, dehydration in spite of cerebral edema, and liver dysfunction resulting in a disturbed carbohydrate metabolism and a decreased activity of the liver as a detoxifying agent We know the resulting cerebral anoxemia, and cerebral edema, the latter producing an increased intracranial pressure, causes excitation of the sympathetic-adrenal centers which will tend to compensate for the anoxia Therefore, cannot the beneficial results obtained in the use of benzedrine sulfate be explained on the basis of its pseudo-sympathomimetic activity as well as its central stimulating property? In chronic alcoholism could we not be dealing with a more latent type of carbohydrate and water metabolism dysfunction, not readily discovered, but producing some irreversible changes? Could not emotional tension due to psychologic factors, in addition to the constant stimulation of the sympathetic-adrenal centers from this cerebral anoxemia, cause a gradual depletion or change of the chemical products that are obtained by the excitation of the sympathetic system? Could not benzedrine sulfate, or some other drug effecting a disturbed metabolism take the place of these depleted chemical products? Some of us have seen benzedrine sulfate take the place of an early morning drink so that a chronic alcoholic could end his present debauch In this case the drug appears to be a surrogate for alcohol.

Could not an individual after he has be-

chronic alcoholics with addiction have been uniformly unsatisfactory

5 *Alcoholic States Complicating Other Mental Illness*—Alcohol may serve as a precipitating factor in the institutionalization of patients with other forms of mental illness. Such individuals who have been drinking may be admitted to the hospital with manifestations suggesting acute intoxication, such as confusion, depression, or excitement. In these patients amphetamine sulfate has been effective in alleviating the symptoms interpreted as acute intoxication unless such manifestations are part of the fundamental pre-existing mental illness which has been accentuated by the alcohol. The bizarre, unclear, clinical syndrome which these cases present on admission to the hospital may be clarified more rapidly by the administration of amphetamine sulfate so that the underlying condition becomes apparent, particularly in the functional states. The depressive after-effects of previous inebriation are dissipated almost as well as in the uncomplicated alcoholic groups. In the presence of organic deterioration from any cause the drug is not effective.

Summary

A series of over 100 cases of alcoholism with and without psychosis has been treated with amphetamine sulfate and compared with a comparable series of consecutive control cases. The results are as follows:

1 In the acute alcoholic psychoses the length of time necessary for recovery was considerably diminished, frequently by half, and the number of recoveries was slightly increased. An aborting tendency of the therapy was cited in the shift of cases from the pathologic intoxication group to the without-psychosis classification.

2 In the protracted alcoholic psychoses tending toward deterioration the results were of very little significance except in the Korsakow's group where a smaller number of cases required commitment after treatment with the drug. An aborting effect was observed in a

shift of cases from the diagnosis of Korsakow's psychosis to the classification of delirium tremens.

3 In the acute phases of alcoholic intoxication amphetamine sulfate has been most effective. Likewise the characteristic physiologic and psychologic after-effects of acute inebriation have been dissipated quickly by the drug.

4 In the treatment of chronic alcoholic addiction with amphetamine sulfate our results have been uniformly unsatisfactory. However, the depression following continuous daily imbibing in these patients responds to the drug during an institutional régime.

5 In alcoholic states complicating other mental illness, amphetamine sulfate at times may be of value in differentiating the states of depression due to alcohol alone, which are usually rapidly dissipated by the drug, from the states of alcoholic depression superimposed on and masking depression of psychogenic origin, which do not respond as readily to the drug.

6 Amphetamine sulfate is of value in the more acute phases of alcoholism with and without psychosis.

Discussion

Dr. Albert B. Siewers, *Syracuse, New York*—I feel that Drs. Davidoff and Reifstein are to be commended on this presentation, particularly on account of the thoroughness of the study, and because it adds one more link to the chain of clinical evidence in the use of amphetamine, and also because it is a study of a medical problem which is too often neglected by medical

ACUTE PANCREATITIS

JOHN J. MORTON, JR., M.D., Rochester, New York

(From the Department of Surgery, the University of Rochester School of Medicine and Dentistry, Rochester)

DURING the ten years following the publication of the excellent review by Schmieden and Sebenius,¹ there has been an increased interest in the problem of acute pancreatitis. Many articles have appeared in the medical literature. Efforts to improve the diagnosis have been recorded. Controversies regarding the proper treatment have divided surgeons into two groups.

This study is based upon the cases of acute pancreatitis that have occurred in the Strong Memorial and the Rochester Municipal hospitals. The clinical impressions and the results of treatment have been abstracted from the records. The files of the pathologic department on pancreatitis have been consulted as well. The pathologists recognize two types of acute pancreatitis at postmortem examination which will not be included in this report. There were 24 cases of acute focal pancreatitis which were coincidental findings in fatal cases of acute infectious diseases, in some degenerative conditions, and as part of the terminal picture in some malignancies. Undoubtedly, a few patients have acute focal pancreatitis with survival. Such cases may be recorded by the laboratory tests now in use in many clinics. It is also fairly common to find acute and chronic pancreatitis of a more extensive character as part of the contributing cause of death. In some instances this acute condition is pronounced, with fat necroses and severe interstitial inflammation. The picture of acute and chronic pancreatitis was recorded in 29 instances. It was noted about equally in failing circulatory states, in malignancies with metastases to lymph nodes in the pancreas region, in carcinoma-tous extensions into the pancreas itself.

Etiology—No attempt will be made to discuss the basic etiologic factors responsible for the behavior of the pancreatic ferments. Nearly every writer on acute pancreatitis has covered this aspect of the etiology. Contributing factors that may lead to the condition may be grouped under several headings.

1 Trauma

- (a) accidental (Table 1)
- (b) surgical (Table 2)
(anesthesia)

2 Infections in Region with Extension to Pancreas

- (a) duodenal ulcer, penetrating head pancreas
- (b) other types (gallbladder, biliary ducts, kidney, ileocecal)

3 Toxic

- (a) alcoholism
- (b) drugs (arsphenamine)

4 Obstructions to Biliary Passages (Partial or Complete)

- (a) stone (Opie)
- (b) spasm sphincter Oddi (Archibald)
- (c) infection
- (d) tumor
- (e) duodenal diverticula
- (f) ascaris

5 Circulatory Stasis

- (a) general (heart failure, hypertensive apoplexy)
- (b) local (thrombosis or embolism of pancreatic vessels)

In this review, examples of nearly every one of these contributing causes have been noted. Accidental trauma may be complicated by this catastrophe. The surgery in the region of the head of the pancreas should involve as little

come an alcoholic continue to need a substitute for alcohol because of irreversible biologic changes that have taken place? These questions are of course speculative, and none of us know the answers at the present time. Nevertheless, we

can see how the results already obtained by Dr Reifenstein and Dr Davidoff may well serve as a stimulation for future research endeavors especially in the direction of a more successful treatment of chronic alcoholism

ACUTE PANCREATITIS

JOHN J. MORTON, JR., M.D., Rochester, New York

(From the Department of Surgery, the University of Rochester School of Medicine and Dentistry, Rochester)

DURING the ten years following the publication of the excellent review by Schmieden and Sebening,¹ there has been an increased interest in the problem of acute pancreatitis. Many articles have appeared in the medical literature. Efforts to improve the diagnosis have been recorded. Controversies regarding the proper treatment have divided surgeons into two groups.

This study is based upon the cases of acute pancreatitis that have occurred in the Strong Memorial and the Rochester Municipal hospitals. The clinical impressions and the results of treatment have been abstracted from the records. The files of the pathologic department on pancreatitis have been consulted as well. The pathologists recognize two types of acute pancreatitis at postmortem examination which will not be included in this report. There were 24 cases of acute focal pancreatitis which were coincidental findings in fatal cases of acute infectious diseases, in some degenerative conditions, and as part of the terminal picture in some malignancies. Undoubtedly, a few patients have acute focal pancreatitis with survival. Such cases may be recorded by the laboratory tests now in use in many clinics. It is also fairly common to find acute and chronic pancreatitis of a more extensive character as part of the contributing cause of death. In some instances this acute condition is pronounced, with fat necroses and severe interstitial inflammation. The picture of acute and chronic pancreatitis was recorded in 29 instances. It was noted about equally in failing circulatory states, in malignancies with metastases to lymph nodes in the pancreas region, in carcinomatous extensions into the pancreas itself.

Etiology—No attempt will be made to discuss the basic etiologic factors responsible for the behavior of the pancreatic ferments. Nearly every writer on acute pancreatitis has covered this aspect of the etiology. Contributing factors that may lead to the condition may be grouped under several headings.

- 1 Trauma
 - (a) accidental (Table 1)
 - (b) surgical (Table 2)
(anesthesia)
- 2 Infections in Region with Extension to Pancreas
 - (a) duodenal ulcer, penetrating head pancreas
 - (b) other types (gallbladder, biliary ducts, kidney, ileocecal)
- 3 Toxic
 - (a) alcoholism
 - (b) drugs (arsphenamme)
- 4 Obstructions to Biliary Passages (Partial or Complete)
 - (a) stone (Opie)
 - (b) spasm sphincter Oddi (Archibald)
 - (c) infection
 - (d) tumor
 - (e) duodenal diverticula
 - (f) ascari
- 5 Circulatory Stasis
 - (a) general (heart failure, hypertensive apoplexy)
 - (b) local (thrombosis or embolism of pancreatic vessels)

In this review, examples of nearly every one of these contributing causes have been noted. Accidental trauma may be complicated by this catastrophe. The surgery in the region of the head of the pancreas should involve as little

TABLE 1—POSTTRAUMATIC PANCREATITIS

trauma as possible in order to forestall such a complication. Surgeons should keep this in mind when faced with such conditions. The occurrence of acute pancreatic necrosis during or directly following anesthesia has been recorded by Cracovaner.² This must be a rare occurrence but it may have been a contributing factor in 2 of our cases. Toxic substances may be partially responsible for the etiology of acute hemorrhagic pancreatitis. Many writers have commented on this aspect.^{3,4} Acute pancreatitis followed heavy use of alcohol in at least 3 of our series. Intravenous arsenicals also have been implicated in some instances.⁵ In 1 of our patients the attack was precipitated immediately after the treatment while the patient was still in the physician's office. The common channel of the biliary and pancreatic ducts (Opie) has been recorded by almost every writer on the subject. There were several instances, clearly demonstrated at postmortem in this series. It is by no means as important a finding as it was once considered.⁶ Occasionally, an interesting bacteriologic study shows how the pancreatic ducts fail to resist organisms under pressure. Holman⁷ reported that the typhoid bacillus which had been present in the gallbladder for twenty years had produced a fatal pancreatitis when a stone blocked the common duct. Rich and Duff⁸ emphasized the peculiar type of vascular necrosis caused by the tryptic ferment when the duct-acinar system had been disrupted through obstruction to the pancreatic secretion. When obstruction has taken place over a long period there may be no effect upon the pancreas even though its ducts be widely dilated. This may be due to absence of

pancreatic secretion or accommodation to the unusual circumstances. It is difficult to explain the report of White and Owen⁹ except upon such a basis. The association of biliary tract disease and acute pancreatitis has been commented upon by many writers. It varies from 20 per cent to 80 per cent. Brody and Custer¹⁰ reported on the degenerative and inflammatory types of acute hemorrhagic pancreatitis.

Pathology—In Fitz's original communication on acute pancreatitis, he called attention to three forms of the condition: the hemorrhagic, the gangrenous, and the suppurative. For many years it has been apparent that there is a less violent form which has been called acute pancreatic edema (Zoepffel). Recently Elman^{11,12,13} has written several papers on this nonhemorrhagic form of pancreatitis. He called it acute interstitial pancreatitis. In one review, gathering 37 cases,¹¹ Archibald, Dan Jones, Stetten, Quick, and Brocq had written on this form of the condition previously. Practically every surgeon of experience has encountered the condition at some time. It was once considered to be the early stage of the acute hemorrhagic variety. The condition then was supposed to progress from edema to hemorrhage to necrosis or massive gangrene to abscess or cystic degeneration. It has been established now without doubt that many cases of acute pancreatic edema never advance beyond that stage but tend rather to regress. Consequently, for evaluation of therapy, two or three distinct groups should be made. In this series an effort has been made to separate acute pancreatitis into three groups: (1) acute edematous pancreatitis, (2) acute hemorrhagic/necrotic

pancreatitis, (3) pancreatic abscess. The basis for this grouping has been made from the description of the pancreas as seen by the surgeon at operation, or as given by the pathologist at the post-mortem examination. There may be flaws in this classification. Some cases of edema of the pancreas have been accompanied by bloody or prune juice exudate and fat necroses, others have lacked one or both of these accompaniments. The pancreas has been greatly enlarged, in part or as a whole in every instance. Sometimes it has been firm, nodular, and tense. At other times it has been soft and boggy. There has been a peculiar translucent greenish edema in the mesenteric, omental, or retroperitoneal tissues in proximity to the pancreas in some cases (Eliason and North).¹⁴ Mild forms of pancreatic edema which would be revealed by laboratory tests have not been included in this report. Although the amylase test has been added to the examinations now being done, our experience with it has been too limited. We have seen and diagnosed clinically a considerable number of cases of acute pancreatitis. These have not been added because they lacked scientific verification. If the diagnosis of the mild forms must rest entirely upon a laboratory test, statistics for this type might best be included in still another group.¹⁵ Consequently, the acute edematous cases reported here have been of the more severe

type. The other two groups which we have made would seem to be self-explanatory.

Symptoms—The symptoms given by the three groups of acute pancreatitis included in this report cannot be used for differentiation of the groups. The milder forms of the edematous variety may give almost similar symptoms but they tend to lessen in severity within a few days.^{13, 15, 16} **Pain** was present in 100 per cent of all types. It has been described as "agonizing," "unbearable," "excruciating," "knifelike," "stabbing," and "colicky." It struck suddenly, severely. It was usually steady, persistent, heavy. Large doses of morphine were required for relief and even failed in some instances. The pain usually started in the epigastrium. It radiated to either costal margin, to the back, to either shoulder or axilla, or to the costovertebral angles. It was of assistance in diagnosis when the pain radiated transversely across the epigastrium to the left. **Vomiting** accompanied about 75 per cent of all types. It usually came early but did not persist. Occasionally, however, it became continuous. Usually it was not progressive—that is, it failed to become fecal. Blood was present in the vomitus on several occasions. **Constipation** was the rule. **Jaundice** was present in about 33 per cent, sometimes a slight icteric tint and sometimes severe and deep. The presence or absence of shock depended

Total of diagnoses made 138
 Acute pancreatitis diagnosed or suspected 24 (17 per cent)

upon the stage when seen by the physician. It was present in some of the cases seen early. About 50 per cent of the patients were described as extremely ill on admission. Cyanosis was present in a few. Twenty-five per cent of these patients gave a previous history of indigestion or discomfort in the epigastric region.

In body habitus, 20 per cent were very fat, and 58 per cent were better than average in stoutness. The temperature was normal, subnormal, or very slightly elevated in most of the early cases. In the same individuals the pulse tended to be disproportionately raised, averaging around 100 F to 110 F. There was, in addition, a white blood count that averaged 17,000 cells. There were 13 individuals with blood counts over 20,000, and only 3 with counts under 10,000.

The outstanding physical sign was tenderness, present in practically all except the very late cases. *Tenderness* was most frequently present in the epigastrium. It varied in position. In the acute hemorrhagic/necrotic group it was present in the epigastrium in 55 per cent, costovertebral in 32 per cent, L U Q and R U Q in 11 per cent, and general, and in the R L Q in 1 per cent each. In the acute edema group it was almost equally distributed over the epigastrium, both upper quadrants, both lower quadrants, generalized, and costovertebral. The left costovertebral angle tenderness was important in assisting toward a diagnosis. *Spasm* was present in about 50 per cent of all cases. *Distention* was prominent in 38 per cent of all cases. In long-standing cases there was a low temperature, a low white blood count, disorientation, lack of vitality, and emaciation.

In a few of the acute cases high blood sugars were recorded. In 1 individual, persistent glycosuria and a blood sugar of over 400 mg was present. It was never completely controlled even by large doses of insulin. Tests for blood or urinary diastase, blood lipase, or tryptic fermentation were not recorded in this series.

Diagnosis—The severe types of pancreatitis are seen so seldom by physicians that the possibility fails to get consideration. The patients in this series were seen by many physicians. If all the diagnoses suggested be taken, and compared with those actually made as acute or suspected pancreatitis it gives an idea of the difficulty. Acute pancreatitis was diagnosed or suspected in only 17 per cent when figured on this basis. The diagnoses most commonly made were acute cholecystitis or cholelithiasis 43, ruptured ulcer 27, intestinal obstruction 8, mesenteric thrombosis 6, ruptured appendix 5, coronary occlusion 5, peritonitis 4, and ruptured ectopic 2. Other diagnoses suggested were gastric crises, bacterial endocarditis, liver abscess, pelvic inflammation, hepatitis, food poisoning, advanced malignancy. All these diagnoses typify a severe type of disease (Table 3).

The diagnosis should be suggested in a given case by the sudden intense pain, the vomiting, the apparent severe blow to the patient, the localization of tenderness, the distention, the absence of fever with the presence of a relatively rapid pulse, and a high white blood count. Shock may or may not be apparent at the time the patient is seen but no one can doubt that something serious has happened. The diagnoses offered are an evidence of this. Excessive obesity with

Twenty two cases with operation 9 died—40.9 per cent mortality

such a picture can be considered additional support for the diagnosis. Tenderness to the left of the midline or in the left costovertebral angle should arouse suspicion. Tests for pancreatic ferments have been advocated as helpful in diagnosis. It has been generally agreed that tests for tryptic and lipolytic ferments have no constant value. Tests for amylase in the blood or urine have been made by many investigators. Their value has been established for the milder and the moderately severe types. The fulminating gangrenous types often may not be demonstrated by these tests.

Differential Diagnosis—This condition must be differentiated from gastric and duodenal perforations. In the latter, there is generally more spasm and splinting of the muscles within a short time from the onset. Some pin-point perforations may be exceptions. Roentgen-ray studies should be made to demonstrate the presence of gas free in the peritoneal cavity.

Intestinal obstructions usually show a progression in vomiting from gastric to biliary to fecal. There is rarely any spasm or marked tenderness early in the course. Evidence of peristaltic activity should be sought, for acute pancreatitis gives a paralytic type of distention. Roentgen-ray studies should be made to determine the extent of intestinal involvement.

Mesenteric thrombosis may be difficult to differentiate, especially if there be blood in the vomitus. The presence of cardiac involvement would favor thrombosis. Bloody vomitus is a bad prognostic sign in either condition.

Coronary occlusions rarely show the initial high white blood count. The blood pressure determinations would be of great assistance. Development of a pericardial friction rub would be helpful.

An aid to differential diagnosis which can be employed is abdominal paracentesis. Recovery of the characteristic prune juice fluid would make the diagnosis.

Treatment—The greatest controversy at present is centered on the treatment of acute pancreatitis. If pancreatic abscess can be diagnosed, there is general agreement that drainage should be instituted. The pancreas can be reached for drainage either through the gastro-hepatic omentum, the gastrocolic omentum, through the foramen of Winslow when the lesser peritoneal cavity is involved, or retroperitoneally.

If the surgeon could be sure of his diagnosis, he might risk a more conservative plan in many cases of the other types. No surgeon need be too proud of his results in the severe types of pancreatitis. But by training, most surgeons would prefer to operate and be wrong in their diagnosis than not to operate and be wrong. Consequently, in case of a doubtful diagnosis it is preferable to operate. In this way, the danger of overlooking perforated ulcers, ruptured appendices, ruptured ectopic pregnancies, gangrenous gallbladders, or gangrenous bowel loops is avoided. Judging from the inability to diagnose pancreatitis from symptoms and signs only, most cases will still fall in this class.

The amylase test may make it possible to differentiate between the edematous and the fulminating severe types. In the former there is a correlation between the concentration of the ferment in the blood and the severity of the disease, in the latter, the test may fail.

Apparently most writers believe that it is safe to watch a *diagnosed* pancreatitis

case although there will be some deaths in any series treated expectantly. We have had this experience in this series. Brocq,¹⁸ Colp,¹⁹ deKlimko,²⁰ Unger,¹ Mikkelsen,²² Kappis,²³ and others also record such instances. Kappis believes that when this occurs it indicates poor judgment in selection, the patients who died being too sick for conservative handling. Judging from reports in the literature, a decided preference for delayed operative treatment has been gaining ground in the last ten years.

Nearly everyone is in agreement that a badly shocked patient should be given the benefit of preparation for operation. He should have his fluid balance restored, be relieved of his pain, and put into the best possible shape for surgery. There will be an opportunity in most cases to take blood for the amylase test, for blood sugar determinations, and for matching for transfusion. Roentgen rays of the abdomen to demonstrate the presence or absence of free air (ulcer perforation) or isolated dilated loops of bowel (intestinal obstruction) can be secured. The vomiting and dilatation of the stomach can be controlled by a Wangenstein tube.

The pancreatic edema patients can be watched to advantage. When the acute attack has subsided, the biliary tract should be drained. This form of the disease is probably due to some obstruction of the pancreatic ducts, according to Cole.²⁴

There has been a fatalistic attitude toward the fulminating hemorrhagic necrotic type of pancreatitis for years. It has become accepted that a certain amount of destruction of the gland is in

compatible with life. Yet every long-experienced surgeon must remember patients who have sloughed out practically the whole pancreas after drainage has been instituted. Such an episode in one of the late Dr. Dan Jones's patients under my supervision is a vivid recollection. Polayes, *et al.*,²⁵ recorded such an instance and referred to a similar case of Colp's.¹⁹ MacKechmie²⁶ has also reported on the sequestration of a large portion of the pancreas. It would appear that such a necrotic piece of tissue should have access to the surface. The basis for drainage operations of the pancreatic area was to allow for the escape of active pancreatic secretions and for the extrusion of dead pancreatic tissue. Drainage should be carried only through the peritoneum over the gland or into definite necrotic areas. Insertion of drains should be done gently in order to limit rather than extend the process. It is practically impossible to incise the pancreas itself for drainage purposes without doing more harm than good. Jones²⁷ used drainage to the pancreatic area in order to relieve the patient of pain and shock. He also considered that it might save the patient from a second operation for abscess. He had seen patients with relatively mild disease unrelieved of pain and shock for a prolonged period when the biliary tract had been drained but the pancreatic area neglected.

When the surgeon has demonstrated

acute hemorrhagic or necrotic pancreatitis, he is faced with the decision as to what procedure he should use. Some surgeons advise that he do nothing but close the abdomen unless the patient has a common duct stone.²⁷ If disease of the biliary tract is present, indications are for drainage of the gallbladder or common duct. Removal of stones may be necessary. Drainage down to the capsule of the pancreas, or through the foramen of Winslow, if the lesser peritoneal cavity is involved, may be useful. As in critical conditions anywhere in surgery, the more ill the patient, the least done to relieve him, the better for all concerned.

Postoperative treatment should consist in complete deprivation of food and water by mouth for three to four days. Wangenstein suction may be employed to advantage. Parenteral fluids should be supplied. Transfusions should be used as necessary. Glucose intravenously may call for insulin to cover it in case the pancreatic damage is severe. Adequate sedation should be employed.

Complications—The surgeon must be prepared to expect a certain number of recurrences of acute attacks. This was noted in 3 of our series. Persistence of a fistula with drainage over a long period will be seen. Pancreatic abscess or pancreatic cyst may form in certain cases. Damage to the pancreatic islands may lead to an actual diabetes but this is relatively rare. There is often surprisingly

little evidence of disturbed pancreatic digestion. In some instances, however, the patient suffers with pancreatic asthenia. He refuses all nourishment and gradually fades in weight and strength. One of our patients lived for forty-four days after operation and then succumbed to this condition. Fatty degeneration of the liver also may be a sequel. The new ferment lipocatic described by Dragstedt may be found useful for this condition.

Results

The different types of acute pancreatitis should be reported separately. The statistics would then have better value. As it is now, the results are given upon acute pancreatitis as a whole. The acute edematous variety is a much less serious disease especially in its milder forms. A composite group of 52 cases from the current literature gave only 3 deaths—a mortality of but 5.7 per cent, whereas a similar but larger group of severe forms gave a mortality of 60.8 per cent.

Results. Acute edematous pancreatitis

	Cases	D	
Elman ¹²	18	0	
deTakats & MacKenzie ²⁹	12	1	
Abell ³⁰	9	0	
Kerschner ³¹	7	1	
Koster & Kasman ³²	6	1	
	52	3	5.7 per cent
Acute hem/nec pancreatitis			
Koster & Kasman ³²	16	4	
deTakats & MacKenzie ²⁹	10	7	
Kerschner ³¹	34	28	
Abell ³⁰	19	9	
Morton	13	8	
	92	56	60.8 per cent

Thus it would seem possible to dilute the actual mortality figures for the severe forms of the disease if enough milder types were included in the series.

That acute pancreatitis of whatever type is a serious disease is illustrated best by the next table of some of the cases reported in the last ten years. These patients were operated upon as surgical emergencies. The figures show a mortality of 49.06 per cent. If these figures are compared with a much smaller group for deferred operation there can be no doubt why the surgeon would choose to be conservative.

INFECTED PARENTS, TEACHERS, AND SERVANTS COMMON SOURCES OF TUBERCULOSIS IN CHILDREN

Childhood tuberculosis is invariably contracted from infected adults in the home and the school, Fairfax Hall, M D, New Rochelle, N Y, warns in the *Journal of the American Medical Association*

The sources of the infection are contact with tuberculous nurses, governesses, maids and other domestic help, teachers, and of course parents, and other adult members of the family

Dr Hall stresses the fact that 'there is a definite hazard to the health of children from intimate association with persons about whom little or nothing is known with regard to freedom from communicable diseases. Since parents are much more apt to have had adequate medical supervision than the servants in a home, the risk to children from the latter is greater. Occasionally an older member of a family, mistakenly thought to have chronic bronchitis or asthma, is

a factor to be considered in safeguarding a child from tuberculosis. School teachers with active tuberculosis are a menace to their pupils

"Contact between children and tuberculous nursemaids or other domestic helpers will be less frequent when parents are so convinced of the necessity of employing only healthy servants that they will demand proof of their servants' health

"Domestics having to do with the care of young children must be persuaded that it is to their advantage to have periodic medical examinations so that they will secure them as a matter of course. When 'health references' are universally asked for and a health card is essential to get a job, a great step forward will have been made. Physicians interested in child health should influence their patients to take this wise precaution for the sake of the children."

NONE FOR US, THANKS

Mustard gas is the most humane and also the most effective weapon a modern army can use, Dr Charles C Denne, of Kansas City, a World War major, told the American Academy of Derma-

tology and Syphilology at a meeting in Philadelphia. It is the most humane gas, he said, because it disables, but does not kill—and seldom permanently injures the victim

BOWEN'S PRECANCEROUS DERMATOSIS OF THE MUCOUS MEMBRANE

Review of the Literature and Report of Two Cases

ANTHONY C CIPOLLARO, M D, New York City, and PAUL D FOSTER, M D, Los Angeles

(From the Skin and Cancer Unit, New York Post-Graduate Medical School, Columbia University)

THIS paper is a report of an investigation of progressive development of Bowen's dyskeratosis of the mucous membranes of the buccal and genital regions. We report for the first time a Bowenoid dyskeratosis appearing upon the tongue. The writers believe that Bowen's disease of the mucous membrane is a more common process than is generally recognized, and call attention to this established entity, reports of which have been confined mainly to the European literature.

Twenty-seven years ago Bowen¹ presented 2 cases of chronic atypical epithelial proliferation which constituted the forerunner to the establishment of the entity now known as Bowen's precancerous dermatosis. In the interim, over 100 similar cases have appeared in the literature. We shall refer here only to those authors who have reported mucous membrane lesions or made some unusual contribution to this subject.

The credit for first recognizing Bowen's disease of the mucous membrane* must go to Jessner,² who in 1921 reported a case involving the proximal and under surface of the prepuce. He described the lesion near the sulcus as a scaly and erythematous hard nodular area which was covered with moderately heavy scales. The microscopic picture was typically that of Bowen's disease.

Hudelo, Oury, and Cailliau³ reported the second case in 1922. The title made no mention of Bowen and it therefore escaped being recorded as such for several years. The lesions involved the mucous

* Some of the cases included in this review are those with penile lesions. We recognize the fact that the glans penis is not mucous membrane.

membrane of the labium majus. No clinical description was given. The histologic report left no doubt as to its being a case of Bowen's disease. The condition was treated by curettage. Subsequent to this treatment there was a rapid spread of the disease to the vulva.

Richon,⁴ in 1925, reported 3 cases of Bowen's disease involving the mucous membranes of the genitalia in females between the ages of 55 and 60 with an average duration of five to ten years. In his thesis, Richon included the case previously reported by Hudelo, Oury, and Cailliau.³ Therefore, only 2 cases should be credited to Richon. He advanced the theory that Bowen's disease has three stages pathologically: (1) a state of pure dyskeratosis, (2) beginning of neoplastic evolution, (3) neoplastic evolution almost complete. He also called attention to the difficulty of early diagnosis and its similarity to erythroplasia of Queyrat. Their differentiation was made possible only by microscopic examination. He has been erroneously accredited with being the first to report Bowen's disease of the mucous membrane.

Kleeberg⁵ in the same year, reported the case of a man, aged 75 years, who had lesions of the prepuce of ten years' duration. The lesion was 2 centimeters in diameter, dark red in color and interspersed with nodules, and margined by an infiltrated border. The treatment was not given. Gutmann's case⁶ was that of a woman, aged 72 years, whose lesions involved the vulva. Delbanco⁷ reported 1 case of Bowen's disease which involved the vulva and the thigh. The

material presented was insufficient to determine whether the case he reported was one of Bowen's disease of the skin or of the mucosa. However, Rousset⁸ who reviewed 18 cases of Bowen's disease of the mucous membranes considered Delbanco's case doubtful. The case reported is that of a woman 59 years old, with lesions on the vulva and the thigh. The microscopic examination was "positive." In his report, Delbanco considers Bowen's disease a precancerous stage of squamous cell epithelioma.

In 1926 Dartigues and Mircouches⁹ presented a patient with lesions upon the labium minus and fourchette, the plaque measured 2.5 centimeters, was slightly elevated and erythematous. Excision resulted in a complete cure. The case reported by Bruusgaard¹⁰ involved the glans penis. The lesion was of long duration and had a papillomatous or warty appearance. The patient was a man, 42 years old. Bloch¹¹ reported a case of Bowen's disease with vulvar lesions, resembling leukoplakia and kraurosis. They varied in size from a pea to a dime, they were erythematous but the centers were whitish. Roentgen radiation resulted in marked improvement. This case is probably the same one described by Sulzberger¹² in his Zürich thesis.

Scomazzoni¹³ presented 3 cases with lesions of the penis. The histologic picture was typical of Bowen's disease. The first one was of one year's duration and showed an erythematous nodular plaque with a definite border. The second case was of four years' duration and gave the appearance of a venereal ulcer. The third case had had lesions for thirty years. It presented multiple papillomas in a small circumscribed area. He gave each of his patients iodides in large quantities and injections of sublimate. The results were disappointing. Asahi¹⁴ reported the case of a man, 31 years old, who had had a lesion for six years on the sulcus of the penis which histologically was shown to be Bowen's disease. The lesion was removed surgically but it recurred on the foreskin. Rusch¹⁵ pre-

sented the case of a woman, 36 years old, before the Vienna Dermatological Society in 1926. She had lesions that involved the labium minus, the perineum, and anal regions. They were red, raised, and papillomatous. The histologic diagnosis was Bowen's disease. The patient also had syphilis. No mention was made of the treatment administered.

In 1928 Szathmáry¹⁶ reported a case of Rusch's¹⁵ of Bowenoid disease involving the labium minus. There were papillomatous and leukoplakia-like lesions. The patient was a young woman, 36 years of age, who had had lesions for eleven years. Three operations were unsuccessful.

A case of Bowen's disease was reported by Guhrauer¹⁷ in 1929. The patient was a woman of 45 years, who had had lesions for about one year on the labium minus. The lesions were infiltrated, elevated, rough, and hyperkeratotic. The treatment was not given. Two cases of Bowen's disease of the mucosa were reported by Arzt.^{18a, 18b} One of these was reported in 1929. The patient was a woman, 40 years old, who had two hard, infiltrated lesions on the internal surface of the left labium majus. Hard nodes were palpable in the left inguinal region. The histologic diagnosis was Bowen's disease. The second case was reported in 1936. This patient was a woman, 57 years old, who had exudative lesions of the anus for ten years prior to examination. She had had for four years a verrucous and horny mass in the left labium minus. The left labium minus showed some thickening and flat papilla-like excrescences of grayish color. The inguinal glands on both sides were enlarged. The histologic diagnosis revealed Bowen's disease.

Nicolas, Massia, and Rousset¹⁹ reviewed 3 cases in detail, 2 of the vulva and 1 of the penis. The lesions were pruriginous, circinate, slightly elevated, erythematous, nonulcerous, and had a small, slightly infiltrated pearly border. Roentgen rays were used in all 3 cases with complete cure in 2. One patient failed to return for observation. On January 23, 1930, Geiger²⁰ presented a

BOWEN'S PRECANCEROUS DERMATOSIS OF THE MUCOUS MEMBRANE

Review of the Literature and Report of Two Cases

ANTHONY C CIPOLLARO, M D , New York City, and PAUL D FOSTER, M D , Los Angeles

(From the Skin and Cancer Unit, New York Post-Graduate Medical School, Columbia University)

THIS paper is a report of an investigation of progressive development of Bowen's dyskeratosis of the mucous membranes of the buccal and genital regions. We report for the first time a Bowenoid dyskeratosis appearing upon the tongue. The writers believe that Bowen's disease of the mucous membrane is a more common process than is generally recognized, and call attention to this established entity, reports of which have been confined mainly to the European literature.

Twenty-seven years ago Bowen¹ presented 2 cases of chronic atypical epithelial proliferation which constituted the forerunner to the establishment of the entity now known as Bowen's precancerous dermatosis. In the interim, over 100 similar cases have appeared in the literature. We shall refer here only to those authors who have reported mucous membrane lesions or made some unusual contribution to this subject.

The credit for first recognizing Bowen's disease of the mucous membrane* must go to Jessner,² who in 1921 reported a case involving the proximal and under surface of the prepuce. He described the lesion near the sulcus as a scaly and erythematous hard nodular area which was covered with moderately heavy scales. The microscopic picture was typically that of Bowen's disease.

Hudelo, Oury, and Cailliau³ reported the second case in 1922. The title made no mention of Bowen and it therefore escaped being recorded as such for several years. The lesions involved the mucous

membrane of the labium majus. No clinical description was given. The histopathologic report left no doubt as to its being a case of Bowen's disease. The condition was treated by curettage. Subsequent to this treatment there was a rapid spread of the disease to the vulva.

Richon,⁴ in 1925, reported 3 cases of Bowen's disease involving the mucous membranes of the genitalia in females between the ages of 55 and 60 with an average duration of five to ten years. In his thesis, Richon included the case previously reported by Hudelo, Oury, and Cailliau.³ Therefore, only 2 cases should be credited to Richon. He advanced the theory that Bowen's disease has three stages pathologically: (1) a state of pure dyskeratosis, (2) beginning of neoplastic evolution, (3) neoplastic evolution almost complete. He also called attention to the difficulty of early diagnosis and its similarity to erythroplasia of Queyrat. Their differentiation was made possible only by microscopic examination. He has been erroneously accredited with being the first to report Bowen's disease of the mucous membrane.

The lesion was 2 centimeters in diameter, dark red in color and interspersed with nodules, and margined by an infiltrated border. The treatment was not given. Gutmann's case⁶ was that of a woman, aged 72 years, whose lesions involved the vulva. Delbanco⁷ reported 1 case of Bowen's disease which involved the vulva and the thigh. The

* Some of the cases included in this review are those with penile lesions. We recognize the fact that the glans penis is not mucous membrane.

epidermal carcinoma of the prickle-cell type with an intact basal layer

On March 20, 1935, Nomland, Skolnik, and Scull²⁹ presented before the Chicago Dermatological Society, a man, 53 years old, who had a plaque-like lesion involving the entire circumference of the prepuce. There were also 3 verrucous lesions in the plaque. The histologic diagnosis was Bowen's disease. The patient also had a 4 plus blood Wassermann reaction. Antisyphilitic therapy had no effect on the lesion. Dr. Hamilton Montgomery examined the histologic slide and made a diagnosis of squamous cell carcinoma, Grade 2, *in situ*.

The 3 cases presented by Howarth³⁰ affected the mouths of men between the ages of 56 and 58 years. The disease had been present in each case, over two years. The structures affected were the lip, cheeks, floor of the mouth, soft palate, fauces, and tonsillar pillars. The 3 cases were similar clinically in that they all presented papillomatous lesions which in 2 cases interfered with swallowing. In 1 case there was enlargement of the cervical glands. The histologic examination in all cases showed Bowen's disease. The 3 patients were treated with diathermic cauterization. In 1 case the lesions recurred and in the other 2 the immediate results were good.

The case reported by Ramel³¹ is that of a woman, 47 years old, who had 3 coin-sized lesions which were elevated, reddish in color, and hyperkeratotic. One lesion was on the clitoris and the other two on the free margin of the labium majus. There was also a lesion in the perianal region. All lesions completely cleared up under roentgen-ray therapy. She received 1,300 r. The kilovoltage was 160, the milliamperage 3, and a filter of 5 mm. aluminum.

Gougerot, Moulounguet, and Lortat-Jacob³² presented a man, 61 years old, with a nummular lesion involving the left side of the palate and extending onto the pillar of the left tonsil. There were some lichenoid lesions in this patch which were discrete as well as in linear formation. The histologic diagnosis was Bowen's

disease. There were no subjective symptoms and no enlargement of the cervical glands.

Touraine and Golé³³ report the case of a woman, 61 years old, who had lesions on the inner surface of the right cheek which resembled leukoplakia. The histologic examination, however, showed Bowen's disease. The lesions had been present for two years. The patient also had cheilitis glandularis with a squamous cell epithelioma in one area. The authors have observed on several occasions that cheilitis glandularis preceded the formation of squamous cell carcinoma. Therefore, according to this observation, cheilitis glandularis may be considered a precancerosis.

Goldberg³⁴ reported 1 case of Bowen's disease affecting the vulva. This patient also showed syphilitic papules of the vulva, leukoplakia and basal-cell epithelioma. Treatment with radium did not prevent the formation of basal-cell epithelioma.

The case reported by Daubresse-Morelle and Dupont³⁵ is that of a woman, aged 60 years, with lesions on the labia minus and majus of ten years' duration. There were large red patches with sharp margins and a hyperkeratotic surface. Subjectively, the patient had considerable pain. Treatment with filtered x-rays produced an excellent result, 2,500 r were given during a period of ten days.

The case reported by Weissenbach, Lévy-Franckel, and Martineau³⁶ was that of a woman, 25 years old, who had lesions extending from the anus to the vulva. The lesions were pinkish, elevated, infiltrated, and ulcerated. The surface was verrucous. Pruritus was especially marked during the menses. The blood Wassermann reaction was negative. It is of interest to note that this is the youngest subject in whom Bowen's disease of the mucosa is reported. Also of interest is the fact that the eruption had been present for two years.

Ferreira Marques³⁷ reported 2 cases of Bowen's disease that were previously presented jointly with E. Urbach before the Austrian Dermatological Society on

case of Bowen's disease of the left labia minus and majus before the Vienna Dermatological Society. The patient was a woman, 62 years old, who had had the lesions for nine months. The lesions were red and papillomatous and were the size of a hazel nut. There was pruritus as well as lesions of leukoplakia. There was one large, hard gland in the left inguinal region. The histology was that of Bowen's disease. The Wassermann reaction was negative. In the discussion of this case, Fuhs²¹ reported that his case had lesions of the left labium minus and later evidences of squamous cell carcinoma developed.

Noguer Moré²² simply mentions 2 cases of Bowen's disease in a report appearing in 1931. In 1 case, the sulcus of the penis is involved and in the other the mucous membrane of the upper lip. No mention is made of age, sex, duration, or treatment.

In his Paris Thesis, Favier²³ reported the case of a man, aged 60 years, who had a lesion on the gum which was diagnosed histologically as Bowen's disease. A few months later this patient developed submaxillary nodes which showed the same histology as the tumor in the mouth. The lesion had been present for one year. Several months after his operation the patient, who was a diabetic in poor general health, died. The author reports this as a case of Bowen's disease of the mouth with metastasis to the submaxillary glands. It is probable that this is a case of metastatic squamous cell carcinoma.

Müller's case²⁴ occurred in a woman, 35 years old, and involved the labium majus and showed senile hypertrophy and a tendency to multiple papillomas. The area affected was sharply margined. Complete cure followed excision of the lesion.

A case of Bowen's disease was reported in 1933 by Rothman²⁵. This patient was presented before the Hungarian Dermatological Society. It was a woman, 56 years old, who had lesions of the vulva. The clinical appearance of the lesions was that of erythroplasia of Queyrat, but the

histologic diagnosis was Bowen's disease. In addition to being operated upon, she was also treated with x-rays. There was no relief from treatment. Five cases of Bowen's disease of the mucous membranes were described by Hudelo and Cailliau²⁶. Two of these cases are new, 2 were described by Richon⁴ in his report of 3 cases, and 1 was originally described by Hudelo, Oury, and Cailliau.³ One case was in a woman who had a lesion involving the nasal mucosa. The lesion was raised, the size of a pea, smooth, and reddish in color. It bled very easily. There was no adenopathy. No mention is made of treatment. The other case was that of a man, 47 years old, who had an almond-sized proliferating lesion that was painful and was situated on the tonsil. The treatment of this case was not given.

Pozzo's²⁷ 3 cases of Bowen's disease of the mucous membranes occurred in patients with glycosuria. The first case was a man, 41 years old, who had syphilis and glycosuria. He complained of pruritus of four years' duration. There was an exudative and crusted eczematous eruption of the prepuce. Phimosis and some infiltration was also present. In places there were lesions resembling prepuccial kraurosis and leukoplakia. The lesion was excised. The second case was very similar to the first one. It was in a man, 46 years old, with involvement of the prepuce. Microscopic examination revealed Bowen's disease. The third case was in a woman, 70 years old, who had a nodular elevation with partial ulceration on the left labium majus. There was no inguinal adenopathy. The microscopic findings resembled Bowen's disease, but there were also features of Paget's disease.

Satenstein and Lewis²⁸ presented before the Manhattan Dermatological Society on February 13, 1934, a man, 28 years old, who had a lesion on the glans penis. The histologic diagnosis was Bowen's disease. Some of the members present did not agree with the diagnosis. J. Frank Fraser examined the slide and stated that Bowen's disease is an intra-

epidermal carcinoma of the prickle-cell type with an intact basal layer

On March 20, 1935, Nomland, Skolnik, and Scull²⁹ presented before the Chicago Dermatological Society, a man, 53 years old, who had a plaque-like lesion involving the entire circumference of the prepuce. There were also 3 verrucous lesions in the plaque. The histologic diagnosis was Bowen's disease. The patient also had a 4 plus blood Wassermann reaction. Antisyphilitic therapy had no effect on the lesion. Dr. Hamilton Montgomery examined the histologic slide and made a diagnosis of squamous cell carcinoma, Grade 2, *in situ*.

The 3 cases presented by Howarth³⁰ affected the mouths of men between the ages of 56 and 58 years. The disease had been present in each case, over two years. FIG 1, CASE 1— $\times 280$ The lesion on the tongue. A hyperplastic epidermis with atypical cells, hyperchromatic nuclei, atypical mitoses and numerous "corps ronds" (benign dyskeratosis). There is loss of stratification and the basement membrane is intact.

May 20, 1937 One case is that of a man, 52 years old, who claimed to have had the eruption for three years. On the dorsum of the penis and prepuce was a plaque-like, exudative, crusted, and infiltrated lesion resembling exudative eczema. The blood Wassermann reaction was negative. The patient was treated with radium with good immediate results, but recurrence took place. A careful study of the biopsy showed squamous cell epithelioma as well as dyskeratosis of the Bowen type. The second case was in a woman, 60 years old, who had a verrucous tumor extending from the left anal region to the left labia minus and majus. This had been present for years. There had been itching for about ten years.

There had been an operation two years previous to presentation but the lesion recurred. The histologic picture was that of an epithelioma of the mixed type (basal-squamous cell epithelioma) with Pagetoid type of reaction. From the clinical and histologic description, it is possible that these might be cases of frank carcinoma.

Stout^{37a} reported 3 cases of Bowen's disease affecting mucous membranes. In 1 case the lesion was situated on the anterior nares, in another on the floor of the mouth with metastases to the cervical and supraclavicular glands, and another involving the vocal cords.

A careful search of the literature revealed 50 cases of Bowen's disease affecting the mucous membranes. Including our 2 cases, the total number is 52, 22 were in men, 29 in women. One author did not give the sex of 1 case. The following sites were affected: penis, vulva, vagina, nose, lip, cheek, floor of mouth, palate, uvula, tonsils, and tongue. The age varies from 25 to 81 years with the average being 51.52 years. The average duration of the lesions was 5.07 years. The most effectual treatment seemed to be a combination of surgical or electrosurgical destruction and radiation (x-rays or radium). Five doubtful cases are included in this summary.

Report of 2 New Cases

Case 1—E. R., a white female aged 60, was seen by Dr. George M. MacKee in private practice on March 21, 1931, complaining of a pinhead-sized nodule upon the left side of her tongue. The lesion was first noticed by her dentist to whom she had gone for an oral examination one month prior to her visit to Dr. MacKee. The dentist recognized it as an unusual lesion and referred the patient for examination and treatment.

Since there were no subjective symptoms, the patient was unaware of its presence and was uncertain as to when it originated. She thought that it might have started as a canker sore which had been irritated by a rough tooth. The tooth had been filed down so that it was perfectly smooth but the lesion remained.

The past history was essentially negative. The patient did not use tobacco in any form. She had no unusual habits nor did she wear a

dental plate She had had psoriasis for thirty-seven years Her sister also had psoriasis for approximately the same length of time During these thirty-seven years she had had many courses of arsenic in the form of Fowler's solution Her general health was excellent

The physical examination except for the psoriasis and the tongue lesion presented no noteworthy findings There were no palpable glands and no jagged teeth The dentition and oral hygiene were very good The tongue was normal except for one isolated lesion upon the left border opposite the last molar This was a nodule about 3 or 4 millimeters in diameter raised, reddened, and firm The summit of the nodule was slightly eroded, the periphery was firm There were no marked inflammatory changes surrounding the lesion A clinical diagnosis of early prickle-cell epithelioma was considered The tongue was anesthetized with 2 per cent solution of procaine and the lesion was excised widely with the high frequency cutting current.

It was felt that irradiation was indicated without waiting for a microscopic report. Dr Merlin Stone inserted 6 gold radon implants of 1 millicurie each in the surrounding tissue approximately 1 centimeter apart. There has been no recurrence to date.

Case 2—S K., a white male, Armenian, aged 55, whose occupation is that of insect exterminator, was first seen in the Dermatological Clinic of the Post-Graduate Hospital on August 21, 1934, complaining of a thickened and pruriginous area just proximal to the corona of the penis upon the dorsal surface. The condition had been present about six months

The past history presented nothing to account for his present complaint except that for the past ten years he had worked as an exterminator. In his occupation he used an arsenic mixture for eight of the ten years. During the last two years he used a mixture of sodium, potassium, and ammonium fluoride. There was no history of syphilis or of other chronic infections The patient denied trauma in this area

The physical examination revealed a healthy middle-aged man. The only noteworthy clinical finding was the lesion on the penis This lesion was proximal to the corona upon the dorsal surface and was 1.5 centimeters in diameter It was infiltrated, raised, circinate, and erythematous The border was somewhat translucent. The central portion measured about 1 centimeter in diameter It was slightly thickened and whitish in appearance, resembling leukoplakia. There were no palpable glands present in the inguinal region. The patient was not circum-

FIG 2, CASE 1— $\times 950$ Higher magnification of Fig 1 showing the details of the abnormal epidermal cells There is marked variation in shape, size, and arrangement of the cells Note also hyperchromatism and clumping of the nuclei.

cised. The genitals were normal in all other respects

Under local procaine anesthesia, the lesion was excised *in toto* The microscopic findings indicated that the lesion had been completely removed. The patient failed to return and all attempts to reach him have been futile as he came to the clinic under a fictitious name and gave an incorrect address

Histopathology

Case 1—Tongue lesion. The specimen consists of a piece of mucous membrane of the tongue in which there is a fairly large patch of acanthosis A sparse round cell infiltration is present. In one area of acanthosis, beginning in the middle of the mucosa, there is a replacement of the old by a newly formed mucosa with its own basal layer and papillae. From the basal layer there is a marked proliferation of epithelial cells which remain for the most part midway differentiated between basal and prickle cells. Toward the periphery of this new growth, the cells differentiate abruptly into prickle cells which again show rather abrupt keratinization. In the more differentiated cells are fairly numerous mitotic figures which show irregular polarity of growth. The nuclei show clumping in some places. Other features of anaplasia such as irregularity in size shape, and staining qualities are also present. Many of the nuclei are quite large and deeply chromatic, the chromatin not

The most effectual treatment seemed to be a combination of surgical or electrosurgical destruction and radiation (x-rays or radium). Five doubtful cases are included in this summary.

Report of 2 New Cases

Case 1—E. R., a white female aged 60, was seen by Dr. George M. MacKee in private practice on March 21, 1931, complaining of a pinhead-sized nodule upon the left side of her tongue. The lesion was first noticed by her dentist to whom she had gone for an oral examination one month prior to her visit to Dr. MacKee. The dentist recognized it as an unusual lesion and referred the patient for examination and treatment.

Since there were no subjective symptoms, the patient was unaware of its presence and was uncertain as to when it originated. She thought that it might have started as a canker sore which had been irritated by a rough tooth. The tooth had been filed down so that it was perfectly smooth but the lesion remained.

The past history was essentially negative. The patient did not use tobacco in any form. She had no unusual habits nor did she wear a

FIG 4, CASE 2 — $\times 950$ A portion of Fig 3 is magnified to show details of the tumor cells. Bowen's "clumping cells," hyperchromatism of the nuclei, mitotic figures and loss of stratification are to be noted.

papillary outgrowth beyond the old corneum. In the most advanced part of the lesion the expansion of the epidermal "pegs" by the new growth compresses the papillae into narrow strands, sometimes pinching off a part or even completely obliterating them. A remnant of the old epidermis can be seen as a narrow band of compressed nuclei surrounding the newly formed epithelial pegs. In no place is there any extension of the new growth beyond the basal cell layer. In conclusion this section shows Bowen's dyskeratosis with proliferation of the squamous cells forming an intra-epidermic, grade two, prickle-cell carcinoma.

Drs. J. Frank Fraser, the late Alexander Fraser, David L. Satenstein, and Fred Weidman studied the slides and agreed with the above findings. Dr. Hamilton Montgomery also studied the sections and concluded that they showed squamous cell epithelioma *in situ*, Grade 2, simulating the picture of Bowen's disease.

In discussing the pathology of Bowen's disease one should keep in mind the original histopathologic findings of Bowen. He reported marked proliferation of the rete Malpighi, karyokinetic divisions and amitosis, clumping of the nuclei, and vacuolization of the cells. In the more advanced lesions, there was edema of the epidermis, hypertrophy of the horny layer, hyper-

keratosis, and parakeratosis with cells not having undergone cornification but showing nuclei surrounded by "membranes" or clear spaces. In the cuts were enlarged vessels surrounded by a cellular infiltrate most of which were plasma cells. The elastic fibers were unchanged.

It is impossible to dwell here at any considerable length upon the individual histopathologic conceptions of the various authors who have contributed to the knowledge of this subject. We shall attempt to summarize the prevailing trend.

There is primarily a hyperplasia of epithelial cells, the features correspond to an intra-epidermic epithelioma with certain peculiar dyskeratotic changes in the proliferated prickle cells. This latter feature segregates this condition into the separate entity "Bowen's Disease." The cells proliferate in all directions, usually beginning with the basal cell but always remaining above the membrana propria. The proliferated cells may be either basal or prickle, usually however, both types of cells are present. They differentiate rapidly and show early keratinization not infrequently as concentric "pearls" and "corps ronds." Individual cells show amitosis and disordered polarity, others show irregularity of outline, size, shape, and the cells appear to clump themselves together. The nuclei and protoplasm stain more deeply than the surrounding normal cells.

FIG 3, CASE 2— $\times 260$ Lesion from penis The epidermis is markedly hyperplastic and basal cell layer is well preserved Many atypical cell forms and marked poikilocarynosis are seen throughout the section In the subpapillary region is seen an inflammatory infiltrate of round and plasma cells

infrequently being broken up into fine granules The old epidermis can be seen as a thin strand covering the outer surface of this new growth Although cells proliferate in all directions they do not break through the membrana propria of the mucosa In conclusion this section shows Bowen's dyskeratosis with proliferation of the squamous cells forming an intra-epidermal grade two, prickle-cell carcinoma

The late Dr J Jadassohn²⁸ briefly examined the pathologic slide of this case when he was in the United States several years ago and it was his opinion at that time that this was not a typical case of Bowen's disease but represented a dyskeratosis of the Bowenoid type, which because of its site of origin would show a somewhat modified dyskeratosis He said that he knew of no other classification in which to place it

Case 2—Penile lesion The epidermis shows a considerable length of marked acanthosis which at one end gradually tapers down to normal width In the papillary and subpapillary layers of the corium of this area is a dense plasma cell infiltration which is most extensive in the most acanthotic area and gradually becomes more and more sparse as the epidermis ap-

proaches the normal The essential feature of the lesion, however, is a replacement in the most acanthotic area of the old by a new epidermis which shows the features of a squamous cell epithelioma This begins as a marked proliferation of the basal cells which spreads out in all directions within the membrana propria They remain midway in differentiation for about one half the extent of their spread and then they differentiate rather abruptly into prickle cells Early as well as advanced keratinization is seen Whorls and pearls are also present Here and there individual cells show an abnormal type of keratinization giving the appearance of the so-called "corps ronds" of Darier These cells also show marked irregularity in growth, polarity, and other features of anaplasia The nuclei show great irregularity in size Some are very large and some show multiplication by amitosis, resulting in the clumping of four to six nuclei in the one large cell There is also marked variation in the density of the nuclear chromatin, some nuclei staining very densely while others are vesicular and frequently fragmented into fine granules New papillae, acting as centers of the same type of growth, appear in many parts of the epidermis In one place there extends a

FIG 4, CASE 2 — $\times 950$ A portion of Fig 3 is magnified to show details of the tumor cells. Bowen's "clumping cells," hyperchromatism of the nuclei, mitotic figures and loss of stratification are to be noted

papillary outgrowth beyond the old corneum. In the most advanced part of the lesion the expansion of the epidermal "pegs" by the new growth compresses the papillae into narrow strands, sometimes pinching off a part or even completely obliterating them. A remnant of the old epidermis can be seen as a narrow band of compressed nuclei surrounding the newly formed epidermal pegs. In no place is there any extension of the new growth beyond the basal cell layer. In conclusion this section shows Bowen's dyskeratosis with proliferation of the squamous cells forming an intra-epidermic, grade two, prickle-cell carcinoma.

Drs. J. Frank Fraser, the late Alexander Fraser, David L. Satenstein, and Fred Weidman studied the slides and agreed with the above findings. Dr. Hamilton Montgomery also studied the sections and concluded that they showed squamous cell epithelioma *in situ*, Grade 2, simulating the picture of Bowen's disease.

In discussing the pathology of Bowen's disease one should keep in mind the original histopathologic findings of Bowen. He reported marked proliferation of the rete Malpighi, karyokinetic divisions and amitosis, clumping of the nuclei, and vacuolization of the cells. In the more advanced lesions there was edema of the epidermis, hypertrophy of the horny layer, hyper-

keratosis, and parakeratosis with cells not having undergone cornification but showing nuclei surrounded by "membranes" or clear spaces. In the cuts were enlarged vessels surrounded by a cellular infiltrate most of which were plasma cells. The elastic fibers were unchanged.

It is impossible to dwell here at any considerable length upon the individual histopathologic conceptions of the various authors who have contributed to the knowledge of this subject. We shall attempt to summarize the prevailing trend.

There is primarily a hyperplasia of epithelial cells, the features correspond to an intra-epidermic epithelioma with certain peculiar dyskeratotic changes in the proliferated prickle cells. This latter feature segregates this condition into the separate entity "Bowen's Disease." The cells proliferate in all directions, usually beginning with the basal cell but always remaining above the membrana propria. The proliferated cells may be either basal or prickle, usually however, both types of cells are present. They differentiate rapidly and show early keratinization not infrequently as concentric "pearls" and "corps ronds." Individual cells show amitosis and disordered polarity, others show irregularity of outline, size, shape, and the cells appear to clump themselves together. The nuclei and protoplasm stain more deeply than the surrounding normal cells.

Some cells are four to six times larger than normal ones and contain shrunken, deeply staining nuclei eccentrically placed. Other cells contain several nuclei. Vacuolization and intracellular edema are constant features. Mitotic figures are abundant. The disorderly arrangement of the cells in the rete Malpighii is very characteristic of all cases of Bowen's disease.

"Grains" which represent broken-up nuclei in the keratinized cell bodies of the horny layer are seen in all cases of Bowen's disease involving the skin.

Heumann³⁹ as early as 1916 mentioned that Bowen's disease is not a precancerosis. In 1928, Fraser⁴⁰ showed conclusively that the process was one of malignancy from inception. Nicolas, Massia, and Rousset¹⁹ in their studies upon Bowen's disease of the mucous membrane came to the conclusion that it was not a pre-epitheliomatous dyskeratosis but a true intra-epidermic cancer from a clinical and especially a histologic standpoint.

The transformation of Bowen's disease from an intra-epidermic to an infiltrating carcinoma has been discussed infrequently. Darier⁴¹ reported a case in which he had observed transformation to an infiltrating carcinoma with metastatic foci. Others to report this were Danel⁴² and Favier.⁴³ Later Fraser reported Wise's case⁴⁴ showing infiltration through the membrana propria. The following findings were significant. The anaplastic cells of the epidermal pegs were broken through the membrana propria and infiltrated the cutis in irregularly shaped buds. It is the opinion of many that Bowen's disease is an intra-epidermic epithelioma and becomes malignant only when it breaks through the basal layer to infiltrate the cutis. A change of Bowen's disease of the vulva to squamous cell epithelioma was reported by Fuhs,⁴⁵ whereas Grütz⁴⁴ demonstrated the formation of a basal cell epithelioma in a case of Bowen's disease. Sequerra and Turnbull⁴⁶ showed the presence of basal and squamous cell carcinoma in Bowen's disease. Civatte⁴⁶ contends that basal, squamous, as well as mixed basal-squamous cell epithelioma may develop in Bowen's disease, although the clinical picture may be the same.

Delbanco⁷ is of the opinion that Bowen's disease is the precancerous stage of squamous cell epithelioma. Montgomery,⁴⁷ however, feels that some ordinary squamous cell epitheliomas of the mucous membrane and other tissues present the histologic features of Bowen's disease. It is a matter of interpretation. If we accept the histologic description of Bowen's precancerous dermatosis as it was given origi-

nally by Bowen, then our 2 cases and others reported are those of Bowen's disease. If one interprets strictly the histologic findings in the light of present-day exactness, Bowen's disease of the mucous membrane can be interpreted as an intra-epidermic epithelioma *in situ* with features of Bowen's dyskeratosis. When the basal cell layer is broken, or when metastases are present the tumor should then be designated as an infiltrating epithelioma. The type of epithelioma depends upon the proliferating cells. Usually these are of the prickle or of the mixed type. This latter stand is justifiable and is a safe one because a case of squamous cell epithelioma would be treated with more thoroughness than one of Bowenoid dyskeratosis. Among others to conclude that Bowen's disease is not a precancerosis but an actual carcinoma *in situ* from its very inception are Hudelo and Cailliau,⁴⁸ and Mantegazza.⁴⁹

From our review of the cases in the literature and from personal communications with students of this subject, and from our own observations of our 2 cases, we agree with those who consider Bowen's disease of the mucous membranes as an intra-epidermic epithelioma. The type of epithelioma that eventually results depends upon the cellular changes that take place. For the most part, however, the cases reported, including ours, show squamous cell epithelioma *in situ*. Grade 2. Some of the reports show clinically papillomatous proliferations in leukoplakic areas similar to many cases of frank carcinoma. Some reports even record enlarged regional lymph nodes, one cannot help but conclude that some cases reported as Bowen's are really those of true carcinoma.

Bowen,¹ Darier,⁴¹ Fraser,⁴⁰ Montgomery,⁴⁷ and others have shown that some cases of Bowen's disease and arsenical keratoses resemble one another histologically. The relationship of arsenic to epithelioma and Bowen's disease has been brought to our attention by Anderson⁴⁷ and Montgomery.⁴⁷ Anderson found large quantities of arsenic in his case of Bowen's disease as well as in cases of multiple benign superficial epithelioma. Among others to report cases of epithelioma, Bowen's disease, and other similar conditions in patients who had taken arsenic in one form or another over a number of years, are Schamberg,⁵⁰ Fraser,⁴⁰ Goldberg,⁵¹ Levin,⁵¹ Ormsby and Mitchell,⁵² Doty,⁵³ Hartzell,⁵⁴ Wende,⁵⁵ Fordyce,⁵⁶ MacKee,⁵⁷ Oliver,⁵⁸ Schwartz and Busman,⁵⁹ Stillians,^{60, 61} Pfahler,⁶² Andrews,⁶³ and Montgomery.⁴⁷ Graham Little⁶⁴ demonstrated the relationship of erythema troid benign epithelioma to psoriasis but failed to indict arsenic as a causative factor. Cheever⁶⁵

reported a case of Paget's disease of the nipple and multiple epithelioma in a patient who had had psoriasis since infancy. It is reasonable to assume that these last 2 cases received arsenic at some time in the treatment of their psoriasis.

In this connection, it is interesting to note that both cases which we report have come in contact with arsenic. The woman had repeated courses of Fowler's solution over a period of thirty-seven years for the treatment of psoriasis. The other case which we report is a man who was employed as an insect exterminator. He came in contact with arsenic-containing insect powders for eight years. He no doubt inhaled and ingested large quantities of arsenic. Pozzo²² brought to our attention the fact that glycosuria may be a cause of Bowen's disease since his 3 cases showed not only glycosuria but pruritus of the genitals. On the other hand, the case of Bowen's disease described by Touraine and Golé,²³ also had cheilitis glandularis. They observed squamous cell epithelioma in 8 out of 11 cases of cheilitis glandularis and suggested the idea that cheilitis glandularis is a precancerosis.

The clinical appearance of this dermatosis as it affects the mucous membranes are nearly as varied as the number of cases reported. The lesions reported were found to fit into three general types: (1) erythroplasia-like, (2) nodular or papillomatous, (3) ulcerative. These clinical types correspond to the 3 pathologic stages described by Richon.⁴ It is, therefore, evident that the differences in clinical characteristics are due to the pathologic stage at which the lesion has progressed. The following is a brief description of the evolution of the clinical stages of Bowen's diseases of the mucous membrane.

1 Early Stage. The lesions are reddish, well circumscribed, glossy, slightly infiltrated, painless, and not ulcerated. Frequently they are covered with a heavy scale. The base of the lesion is soft. Slight pruritus may be present. The general health is good and the regional nodes are not enlarged.

2 Latent Stage. The lesions may remain as in the early stage for a long period. Changes may occur extremely slowly. The lesion tends to become nodular and even papillomatous in this stage and is frequently covered with a mucoid substance which causes crust formation. The base of the lesion becomes infiltrated to a noticeable degree. There is a tendency to eczematization and frequently ulceration.

3 Late Stage. The nodular or papillomatous areas tend to ulcerate. The base becomes deeply infiltrated. Glands may become palpable and it is in this stage that metastases occur.

Treatment—If a tentative diagnosis of Bowen's disease is made of a lesion on the mucous membrane, we advise prompt treatment. The area around the lesion should be thoroughly anesthetized with procaine solution. The whole lesion or a portion of it should be removed with scalpel or skin punch and sent to the laboratory for histologic examination. The entire affected area should then be destroyed by radical scalpel excision or by electrosurgery. We believe that postoperative irradiation with roentgen rays, radon seeds or radium element needles or plaque will assure success of the operative procedure and will prevent recurrences. If the condition has already become invasive and involves regional nodes, then radical treatment for metastatic carcinoma should be instituted. We advise against treating these lesions with caustics, electrolysis, ultraviolet radiation, or with solid carbon dioxide. They should be treated adequately and radically at the very start. Improper treatment may activate a relatively benign process into a malignant one.

Summary

1 Two cases of Bowen's precancerous dermatosis of the mucous membrane are reported, 1 of the tongue and 1 of the penis.

2 A clinical diagnosis of Bowen's disease of the mucous membrane cannot be made with certainty. It can only be suspected and then confirmed microscopically.

3 The histopathology shows dyskeratosis typical of Bowen's disease and an intra-epidermic or infiltrating epithelioma of peculiar cellular characteristics. These changes are undoubtedly present from the inception of the lesion.

4 Arsenic may play a role in the etiology of Bowen's disease.

5 The literature on this subject is reviewed.

. . .

We are indebted to Dr MacKee for permitting us to report 1 case from his private practice and 1 case from the clinic, and to the late Drs J. Jadassohn and Alexander Fraser, as well as Drs J. Frank Fraser, David L. Satenstein, Fred Wedman, and Hamilton Montgomery for their help in interpreting the histologic slides.

Discussion

Dr Timothy J Riordan, New York City— Besides reporting 2 cases of cancerous Bowen's disease, of which 1 is a "first," namely, the case involving the tongue, the authors offer a praiseworthy piece of work in reviewing the literature of the condition affecting mucous membranes. Since the final diagnosis of many diseases of the mucous membranes including the one under discussion depends on the interpretation of the microscopic findings and since there are some differences of opinion in the histologic interpretation, this review is timely. If we break down the review from the standpoint of the pathologic reports, we note that most of the cases reported contain no more than mere mention of the fact that the microscopic examination showed Bowen's disease. A few intimated epitheliomatous changes and a few reported epitheliomas with the change characteristic of Bowen's disease. Unquestionably the information given by Bowen originally was not defective. The reports following Bowen did not contain defective information. The question arises, however, whether in some cases the information, though not defective, could have been incomplete. The concept that lesions of Bowen's disease are cancerous from incipency was promulgated some years back and I believe it is gaining adherents right along. In my own training under the late Drs. W J Highman and

Alexander Fraser, I was brought up, so to speak, with that concept. Mention was made of Dr J Frank Fraser's work proving that concept. It is cause for wonder how many cases with features of Bowen's disease have been diagnosed histologically as epithelioma and remain so classified because features of Bowen's disease present were considered secondary. I recall one such case in my limited experience. What I am trying to express is that in the light of our present attempts at exactitude, we may be confusing the issue because of improper classification. And so to me at least, it is a challenge to the histopathologist. The clinician can expect a varying report just as the breakdown of this review revealed varying reports for the same condition. And in the beginning, I said the authors report 2 cases of cancerous Bowen's disease, but we must read the reports to find out.

As to arsenic playing a role in the etiology, I have nothing to say except that the accumulation of cases in the literature where arsenic was ingested creates the impression that it plays a role. We can't accept impression as fact.

As to treatment, the fact that the lesion affects the mucous membranes and may become malignant cancer even unto metastasis and death although remaining in a stationery phase for a long time, merits serious judgment in dealing with it. If we biopsy the lesion, we must destroy it entirely and if the lesion is confined to the epidermis, surgery or electrosurgery is enough. The destruction should extend a little beyond the border. This disease is an example of one that can be adequately destroyed by the so-called "hot-nail" treatment. Often these lesions well circumscribed clinically may show change a little beyond the border. In dermatologic practice we feel more secure perhaps in following the destruction with the use of x-ray.

Dr Marion B Sulzberger, *New York City*—We must all be indebted to the presenters for their excellent historical survey of cases of Bowen's disease of the mucous membranes.

Dr Cipollaro has been quite right in stating that the case which formed the subject of my thesis to acquire the doctor degree at the University of Zürich, in 1925, was one of a combination of Bowen's disease, leukoplakia, kraurosis, cancer, and pruritus of the vulvar mucous membrane. Dr Delbanco of Hamburg later called attention to the frequency of the combination of kraurosis and leukoplakia. As Dr Cipollaro further stated, the case which I worked up in my doctor's thesis was the same as the one presented at a medical meeting by my chief, Professor Bloch. In this 80-year-old woman, all attempts at therapy were unavailing, until a permanent cure was effected by complete vulvectomy.

Regarding the question of *precancerosis*, whether or not one calls a condition a precancerosis depends greatly upon one's definition of cancerosis or cancer. If one considers a condition which is *noninfiltrating*, produces little or no inflammatory reaction, in many cases never metastasizes, in many cases never destroys the local tissues, in many cases remains quiescent, localized, and entirely benign for many years, or for the lifetime of the patient—if one calls such a condition a "cancer," then one can speak of Bowen's disease as a cancer. But if one does not consider that the description I have just given characterizes "cancer," then Bowen's disease is not a cancer. Nevertheless in the majority of these lesions, provided the patient lives long enough, a true, typical, metastasizing, destructive, and malignant lesion eventually supervenes. And this is in my mind the real meaning of the term "precancerosis"—a lesion which as a rule is not itself malignant but in which as a rule malignant changes will eventually occur.

THOSE FIRST IMPRESSIONS

When your patient is delayed in your waiting room, he has a chance to make a few observations. The housewife will note the cleanliness and order of the surroundings. She will observe the draperies, the condition of the decorations, the pictures on the walls, the floor coverings, the lighting effect, the furniture. If she is a new patient, while she waits she formulates some rather definite ideas about the man whom she is soon to meet and to whom she is about to commit her case—he is clean and sanitary or sloven and careless, he is orderly and systematic or hap-

azard and negligent, she is favorably impressed or critically suspicious before she has even seen her physician, she is predisposed to like him or not like him. And to give further detail to the picture, the secretary may add some bold color—a pleasant or an irritating manner, a tell-tale conversation over the phone, etc. A good or a bad psychology has been created while your patient waits, a factor not wholly unrelated to the success of your later treatment.—*Stanley R Mauck, Exec Sec, Columbus Acad of Med, in Ohio State M J*

THE VALUE OF STEREOSCOPIC PNEUMOGRAPHIC STUDIES IN THE DIAGNOSIS AND LOCALIZATION OF RENAL AND URETERAL CALCULI

W W SCOTT, M D , and JOHN A BENJAMIN, JR , M D , Rochester, New York

(From the Department of Surgery, Division of Urology, University of Rochester School of Medicine and Dentistry, Rochester)

IN A limited number of cases of renal lithiasis, our present methods of x-ray study may not only fail to prove the presence of a stone but also may be of little or no value in locating, with any degree of accuracy, the position of a renal or ureteral calculus. Frequently, a plain abdominal roentgenogram is of questionable aid in those cases of renal lithiasis in which the density of the stone is quite similar to that of the soft structures of the body. Furthermore, in such cases, the use of any of the more popular kinds of pyelographic media, in an attempt to confirm the diagnosis by means of a negative shadow at the site of the calculus, may prove quite disappointing. In those cases of renal or ureteral lithiasis in which surgery is indicated, an exact preoperative knowledge of the location of the stone is most desirable. All too frequently, because of the marked similarity in density of the calculus and the more frequently used types of pyelographic media, such information cannot be obtained.

With the hope of developing a method that would give us more positive information with reference to the presence and location of renal and ureteral calculi in those cases in which our routine procedures failed, we decided to make a comparative study of the density of the more common types of renal calculi and the more popular kinds of pyelographic media (Table 1).

From this study, we were impressed by the contrast value of air as a pyelographic medium in selected cases. Furthermore, air is readily available and costs nothing. Because of the reported

deaths following inflation of the bladder (Mathé) and following perirenal insufflation (Hyman and Wilhelm) we felt that additional investigations should be made before attempting its clinical use.

The use of air and other gases in the study of the urinary tract is not new. Keller,¹ in 1904, was the first to use air to study pneumocystadiography. Burkhardt and Polano,² in 1906, while studying pneumocystadiography, were the first to suggest using oxygen to fill the renal pelvis in order to detect the presence of calculi. Von Lichtenberg and Dietlen,³ in June, 1911, were able to demonstrate on the x-ray film the presence of renal calculi by the use of oxygen as a contrast medium. At the suggestion of Willie of the Mayo Clinic, Cole,⁴ in October, 1911, carried out pneumopyelography on a case of marked hydronephrosis with a questionable stone shadow. He was able to rule this shadow out with the aid of stereoscopic pneumopyelograms. He pointed out that it was not necessary to insert the catheter all the way to the pelvis, that air accentuates the calculus shadow and air can be readily withdrawn, and that what little remains is probably absorbed without harm to the patient.

Granger⁵ reported 2 successful cases in 1916. Thompson,⁶ in 1922, used oxygen under a pressure of 180 mm Hg in a case of hydronephrosis without reaction. He felt that after the patient has discomfort on the side being investigated, an additional pressure of 20 mm Hg should be used to obtain satisfactory detail of the pelvis and calyces. He also noted that after a certain pressure the

*Read at the Annual Meeting of the Medical Society of the State of New York
Syracuse, April 25, 1939*

oxygen would escape alongside the ureteral catheter to the bladder, thereby giving a means of regulating the intrapelvic pressure and lessening the probability of an air embolus. Clark,⁷ in 1923, followed the technic outlined by Thompson Braash⁸ reproduced in his book on urography an excellent air pyelogram showing a stone. He claims that it is too difficult to fill the pelvis completely and to differentiate the pelvic outline from gas in the surrounding bowel. Eichler,⁹ in 1935, while studying extravasation in the kidney, in conjunction with pyelographic media, used oxygen for contrast. In 1938, Hughes¹⁰ reported a series of 500 pneumopyelograms without serious reaction.

In 1867, Demarquay¹¹ found that oxygen could enter the vein directly without endangering the life of the dog. Gärtner,¹² in 1902, and Stürtz,¹³ in 1903, showed that oxygen could enter the vein directly, and that one-fifth of the normal oxygen requirements for fifteen minutes could be injected without killing a dog. Lewin,¹⁴ in 1898, found that when compressed air was forced through a water suspension of methylene blue and gum arabic, the presence of air seemed to facilitate the passage of the suspension into the renal tubules, lymphatics, and vessels. Nicholich,¹⁵ in 1913, thought that air entered the circulation of the kidney after it had passed from the bladder up the ureter to the pelvis. Santini,¹⁶ the same year injected air under considerable pressure into the dog's bladder, and found that the normal bladder would rupture before air would enter the kidney pelvis by way of the ureter. Graves and Davidoff^{17, 18} showed, however, that fluids will pass from the bladder into the kidney pelvis by way of the ureters. Poddighe,¹⁹ in 1914, was unable to confirm the observations of Santini. Furthermore, he was unable to produce death from air embolism in the dog by injecting air into the ureter to the kidney under considerable pressure. Postmortem examination revealed huge dilation of the pelvis, calyces, and tubular system, and compression of the glomeruli,

TABLE 1

Density of Calculi		Density of Media	
Uric acid	0.97	Air nitrogen-oxygen	0.001
Xanthin	1.00	Water	1.00
Cystin	1.18	*Water (distilled)	0.997

Calcium phosphate	1.25	*Skodan 15 per cent sol	1.11
Calcium carbonate	1.33	*Diodrast (i.v.) 35 per cent wt./vol	1.18
Calcium oxalate	1.36		

* The writers are greatly indebted to Dr. H. C. Hodge of the Department of Biochemistry and Pharmacology for his work in the determination of the densities of these media. Data on density of calculi taken from Köhler.

but the air was not found in the cardiovascular system. He also found that if the veins of the bladder were traumatized, air inflation of the bladder would lead to death from embolism in a few minutes.

Thomas and Sweet,²⁰ in 1923, found that if air was injected by way of the ureter into the pelvis of a dog it would enter the venous system at a pressure of 150 to 200 mm Hg. Hinman and Lee-Brown²¹ have showed that solutions are also readily absorbed by the veins of the pelvis. Fuchs,²² and Burger and Fuchs,²³ in 1927, found that if air was injected into the pelvis by way of the ureter of rabbits the pelvis would gradually dilate, and suddenly air bubbles could be seen in the renal vein after entering the venous circulation of the calyces. The animal died within a few minutes. They believed that the resorptive power of oxygen in the venous system was not sufficient for protection against fatal emboli.

After reviewing the literature and critically taking into consideration the possibility of air embolism, which had been the constant fear of workers in the past, we undertook a series of experiments on dogs.

Six female dogs were studied, using nembutal for anesthesia, giving 25 mg per kilogram intravenously. The bladder was opened suprapubically and a catheter passed to each kidney (Fig. 1). Three different experiments were performed on each dog.

Experiment 1—The bladder was filled with sterile saline solution so that the ureteral orifices were completely immersed. A catheter was passed to each

kidney, manometer attached, and air forced to each pelvis. If the pressure in the renal pelvis was sufficiently high, the air would return down the ureter to the bladder. In order to produce this, it was found that on the average of 11 cc of air under an average pressure of 70 mm Hg for three minutes was required.

Experiment 2—Ureteral catheters were passed, the ureters and kidneys exposed, and ties placed around the ureters in order to prevent a return of air to the bladder. When air was passed through the catheter it was found that the ureter and kidney became enlarged and tense, and suddenly small foamlike air bubbles began to pass through the renal vein (Fig. 1). The average conditions required to produce this were an average volume of 28 cc of air under an average pressure of 170 mm Hg for seven minutes.

Experiment 3—Experiment 2 was repeated on dogs within an hour after they had been sacrificed. The average volume of air required was 15 cc under an average pressure of 75 mm Hg for four minutes. It is at once obvious that experiments performed on dead structures may be misleading.

Although the series was small, the results obtained were so uniform in character that one felt justified in drawing certain conclusions concerning the clinical possibilities of pneumopyelography. The results in the above experiments varied little if any with different types and sizes of catheters. It was found that satisfactory pneumopyelograms could be obtained on dogs under a pressure of 20 to 30 mm Hg. It is evident from the pressure range in the above experiments that the margin of safety is such that little risk would attend clinical application.

Method

The patient is prepared in the usual manner for cystoscopy, and we have the manometer of the Wappler cystometric set in readiness for use. Ureteral catheters, preferably number 7 whistle tip, are passed. After specimens, cultures, and differential phenolsulfonphthalein

studies have been made, pneumopyelograms are obtained.

A 20 cc. Luer syringe with a tight fitting barrel is connected with a T tube which leads to the manometer and the ureteral catheter (Fig. 1). The syringe can be used with greater ease and the leakage of air around the barrel can be prevented if the plunger is lubricated with sterile glycerine before the air injection is started. The air is injected very, very slowly, at a pressure of 20 to 30 mm Hg, until the patient experiences very slight pain. If the pressure tends to rise above 30 mm Hg, the tension on the barrel of the syringe is lessened until the pressure returns to the desired level and the procedure is continued again as described above. As our experience with pneumopyelography increased, we were able to estimate pressure fairly accurately without the aid of the manometer and we discontinued its use. When desired, as much of the air as possible can be immediately withdrawn and retrograde skioldan pyelograms obtained. It was found that the pneumopyelogram could be followed immediately by a pyelogram with skioldan with no increase in the reaction on the part of the patient.

Observation from Clinical Studies

In the clinical group, 95 patients were studied and pneumopyelography was performed in different upper urinary tract conditions, namely renal calculi with and without hydronephrosis, hydronephrosis, pyelitis, tuberculosis, polycystic kidneys, and ureteral calculi. In this group were 39 males and 56 females, varying from 16 to 71 years of age. The cases with essentially normal pelvis and slight hydronephrosis required an average of 12 cc. of air under a pressure of 20 to 30 mm Hg, where there was marked hydronephrosis, more air under the same range of pressure was necessary to fill the pelvis. One case required 120 cc of air to elicit slight pain, and we were able to rule out definitely suspected cholelithiasis by means of stereoscopic pneumopyelogram. We concluded that pneumopyelogram

FIG 1. Diagram of dog experiments (a) Method of controlling pressure and measuring volume, (b) exposed bladder filled with saline solution, (c) ligature around ureter was pulled tight in experiment 2 to prevent return of air to bladder, (d) passage of air bubbles through renal vein in experiment 2

raphy is best suited for cases in which one suspects or is dealing with calculi, while in the other conditions mentioned above, the media in common usage are to be employed. The following cases, with brief history and figures, are representative of our clinical study of those patients in which we were dealing with calculi.

Case 1—A A, female aged 45, on admission complained of pressure in the abdomen and sharp pain in the region of the right hip. She was anemic and was tender in the right lower quadrant, and the right kidney was palpable. Studies of bladder urine were negative. Blood chemistry studies and phthalein test were normal. X-ray of the abdomen showed two shadows over the region of the right kidney compatible with renal calculi (Fig 2a). The phthalein output for thirty minutes was 15 per cent for each kidney. Bilateral stereoscopic pyelograms using skiodan showed marked hydronephrosis of the right kidney with stricture of the ureteropelvic junction and high insertion of the ureter into the pelvis (Fig 2b). Bilateral stereoscopic pneumopyelograms showed two calculi, one in the pelvis and one at the mouth of the inferior calyx (Fig 2c). A Foley Y plastic operation, pyelolithotomy and nephropexy were performed and the post-operative course was uneventful.

Case 2—G C, female aged 57, complained of pain in the right thigh, pain over the bladder nocturia, and a weight loss of thirty pounds in two years. She was anemic, had myocardial

changes, and the right kidney was palpable and tender. Blood chemistry studies and phthalein test were normal. Urine showed many pus cells and *Escherichia coli* was grown from it. X-ray of the abdomen showed bilateral renal calculi (Fig 3a). The left kidney urine showed *Escherichia coli* on culture, and the phthalein output for thirty minutes was 30 per cent on the right side as compared to 25 per cent on the left side. Bilateral stereoscopic pyelogram using skiodan showed bilateral hydronephrosis with narrowing of the left ureteropelvic junction (Fig 3b). Bilateral stereoscopic pneumopyelogram showed that the calculi in the right kidney were located in the three dilated lowermost calyces and kidney pelvis, while in the left kidney one stone was found in the dilated superior calyx, one in the pelvis, and three in the inferior calyx (Fig 3c). Because of her poor physical condition, she was placed on palliative treatment consisting of mandelic acid therapy and dilations of the left ureteropelvic junction with pelvic lavage. She is responding very well. The stones in the left kidney will be removed and a plastic operation will be performed in the near future.

Case 3—F O, female aged 51, on admission complained of intermittent pain in the right upper quadrant for eight months frequently urgent, and burning. Her heart was moderately enlarged and she had tenderness over the right kidney region anteriorly. Her urine showed a few pus cells and *Escherichia coli*. Blood chemistry studies and phthalein test were

FIG 3, CASE 2 (a) Flat plate showing shadows in region of both kidneys, (b) bilateral hydro-nephrosis with obstruction at left ureteropelvic junction, localization of calculi not definite, (c) stereoscopic pneumopyelogram showing exact location of renal calculi

normal X-ray of the abdomen showed two shadows in the right kidney region (Fig 4a) *Escherichia coli* was grown from the urine of the right kidney, and the phthalein output for thirty minutes on the right side was 10 per cent as compared to 45 per cent on the left side. Bilateral stereoscopic pyelograms using skiodan showed hydronephrosis and hydroureter on the right side with some tortuosity of the ureter (Fig 4b). Bilateral stereoscopic pneumopyelograms showed two calculi in the mouth of the two major calyces (Fig 4c). In view of her age, poor phthalein output of the right kidney, and infection with *Escherichia coli*, nephrectomy was performed with an uneventful postoperative course.

Case 4—B S, female aged 31, on admission complained of pain in the left flank, frequency urgency, and burning. She was under treatment for syphilis and stated she had had pyelitis on the left side a year previously. There was slight tenderness in the left costovertebral angle. Her urine contained pus cells and *Escherichia coli*. X-ray of the abdomen showed a very indistinct shadow in the region of the upper pole and a fairly well-defined shadow in the lower pole of the kidney, suggesting calculi (Fig 5a). The phthalein output in thirty minutes was 20 per cent from the right kidney and 25 per cent from the left. Bilateral stereoscopic pyelogram using skiodan obscured both shadows, thereby confusing the picture from the standpoint of

FIG 4, CASE 3 (a) Flat plate showing shadows in kidney region, (b) and (c) note localization of stones in pneumopyelogram (c) as compared with pyelogram with denser medium (b)

FIG 5, CASE 4. (a) Arrows point to questionable stone shadows in flat plate, (b) and (c) contrast pyelograms with skiodan and air, the latter accentuating and localizing questionable shadow in upper pole

diagnosis and localization of the calculi (Fig 5b) Bilateral stereoscopic pneumopyelogram not only accentuates the shadow in the upper pole, but also definitely localizes both shadows and leaves no question as to the diagnosis of renal calculi (Fig 5c) She was placed on palliative treatment consisting of mandelic acid therapy and high vitamin acid ash diet

Case 5—J R, male aged 51, on admission complained of sudden and severe pain in the left flank seven hours before admission He had experienced similar attacks during the past year Urine showed a few pus cells, a few red blood cells, and staphylococcus albus Blood chemistry studies and phthalein test were normal X-ray of the abdomen showed a shadow in the lower right ureter and in the upper left ureter, compatible with calculi (Fig 6a) Staphylococcus albus was grown from the urine of each kidney and the phthalein output for thirty minutes was 20 per cent for either kidney Bilateral stereoscopic pyelogram using skiodan showed early hydronephrosis in the left kidney (Fig 6b) Bilateral stereoscopic pneumopyelogram showed a stone in the upper portion of the left ureter (Fig 6c) Left ureterolithotomy was performed with an uneventful postoperative course The stone in the right ureter was removed by manipulation with catheter, bougies, and instillation of 2 per cent avertin

Discussion and Summary

The writers are of the opinion, from their own experimental and clinical observations and from a study of the results

obtained by others, that pneumopyelography is safe if one observes the precautions that were pointed out under the discussion of the method

It is at once evident that air is the cheapest of all pyelographic media

Although we do not advocate the routine use of pneumopyelography, we believe that there are certain conditions that have to do with the diagnosis and location of renal and ureteral calculi in which stereoscopic pneumographic studies will give information that cannot be obtained by other methods In those cases of renal calculi in which the stone shadow in the flat x-ray plate varies so slightly in color from the shadows cast by the soft tissues in its immediate neighborhood that there is grave doubt as to whether or not a stone is present, stereoscopic pneumopyelograms so accentuate the stone shadow that there can be no question as to diagnosis

Also, in those cases in which the surgical removal of the calculus is contemplated, the difference of density between the more common types of renal and ureteral calculi and air is usually such that pneumopyelography gives the operator a much better idea of the exact location of the stone or stones than could be obtained by the use of a denser medium Such preoperative knowledge shortens

Discussion

Dr Augustus Harris, Brooklyn, New York—
Dr Scott has demonstrated, not only by experi-

ments on dogs, but also by clinical application in 95 patients, that pneumopyelography is a safe procedure

Fear of the possibility of complicating air embolus undoubtedly explains why this method has not been more generally adopted as a diagnostic procedure, at least in selected cases. The writer has never injected air into the renal pelvis

We can agree that nonopaque and faintly opaque calculi in the ureter, pelvis, and calyces not infrequently fail to be demonstrated. Pain has often been typical of reno-ureteral obstruction in cases where careful studies have definitely excluded other pathologic forms of obstruction

To be sure, the value of the wax-tipped filiform bougie must not be overlooked in obtaining a scratch in ureteral stone. Phosphatic, uric acid, urate, and other putty-like stones may either fail to be seen or their actual number may not be determined. It is in this type of case that air injection should offer its greatest field of usefulness. Where possible, the actual number of calculi present in the kidney should be known before surgery is attempted. Air obviously offers greater contrast to shadows than any other medium now employed. In spite of improved radiography, we believe that 15 to 25 per cent of small calculi may fail of demonstration under present methods

Manometric control of air pressure as prescribed by Dr Scott, if carefully used, should afford the operator greater assurance of its safety. We believe Scott's method deserves special study and a fair clinical trial

Dr Elmer Hess, Erie, Pennsylvania—Anyone who knows Winfield Scott knows how thoroughly he goes into a given problem and realizes that his conclusions, as a rule, are sane, conservative, and constructive. The method with which he has approached the pneumopyelogram evidences the value of animal experimentation before clinical trial is attempted. It has been my privilege to attempt pneumopyelograms in several instances without benefit of this experimentation, and in rare cases have I found some diagnostic help from this procedure. The fear of air embolus seems to be more of a theoretic deterrent than an actual one, and I myself have

never seen such a complication following aerograms or pneumopyelograms. My experience has been limited to just a very few patients and for that reason I am not qualified to discuss this type of diagnostic procedure with too much authority. It does seem that in certain types of renal and ureteral calculi a carefully done pneumopyelogram will be of valuable diagnostic aid, particularly in those cases which ordinarily do not show a stone by a plain film. This is another very valuable contribution to our diagnostic armamentarium. The work has been thoroughly done and the conclusions are conservative and sound.

TO DOT THE STATE WITH TUMOR CLINICS

The establishment of a chain of tumor clinics in strategic centers in the upstate area is one of the major goals of the new state cancer control program which is being administered under the supervision of Dr Louis C. Kress, director of the recently reorganized Division of Cancer Control, says *Health News* (Albany). The clinics will be so located that a patient anywhere in the state need not travel more than fifty miles from his community to procure adequate treatment. At present there are twenty-six such units upstate, and several more are in process of organization. *Health News* will publish, in the near future, a complete list of these clinics together with information as to procedure in obtaining services.

So far as possible, each clinic will be organized according to standards established by the American College of Surgeons. Consultants will be provided to aid clinic staffs in diagnosing and treating the disease and to render consultant service on request to local physicians. A complete and up-to-date record of x-ray and radium equipment throughout the state will be maintained so that needs may be determined and aid given,

where possible, in obtaining adequate therapeutic facilities.

Another feature of the new program is the reporting of cancer, effective January 1, of this year, which will make available more accurate mortality and morbidity records with respect to site, type, occupation, age, sex, color, and geographic distribution. Reporting is expected to shed light on many obscure points regarding the occurrence of human cancer. Cases are already being reported at the rate of about forty a day.

The Division of Cancer Control plans to hold meetings at which physicians, surgeons, radiologists, pathologists, and other specialists in cancer control may assemble and discuss individual problems. It will also sponsor a program of popular education designed to acquaint laymen with the symptoms of cancer and the importance to patients of seeking immediate medical attention at the first indication of the disease.

Through the application of these and other measures it is estimated that at least 2,300 lives may be saved each year in the state outside of New York City.

SALVAGING FACIAL WRECKAGE

For centuries it has been the custom in India for a husband, discovering his wife unfaithful, to cut off her nose. The ancient surgical technique of replacing the noses of these indiscreet wives is still used by the plastic surgeon, who today must replace noses cut off in automobile accidents. Dr. Claire L. Straith, of Detroit, plastic surgeon, told members of the Buffalo Academy of Medicine, meeting in the Buffalo Museum of Science, recently.

A flap of skin is cut from the forehead and laid over the nose structure until the skin adheres. Then the surplus is clipped off and put back on the forehead. Modern women, who usually wear their hair low over the forehead thereafter to hide a slight, resulting scar, are merely following a precedent set by ancient Indians, the doctor explained. In ancient Italy physicians grafted

skin on noses by tying one of the patient's arms up to his nose, but this method has been abandoned.

Dr. Straith illustrated with many pictures the method of building new noses and brought a local woman to the platform to show the finished result.

The most horrible facial disfigurements today result from automobile accidents, the Detroit surgeon reported, adding that 80 per cent of those disfigured are passengers in the right front seat. He criticized some automobiles having instrument panels bristling with knobs and protruberances, which, he said, rip faces and smash skulls. Automotive designers are making safer instrument panels now, he reported. He recommended the use in automobiles of crash padding such as some airplanes have.

THE MODE OF ACQUISITION OF LYMPHOGRANULOMA VENEREUM OF THE ANORECTAL TYPE

ARTHUR W GRACE, M D , New York City, and GEORGE W HENRY, M D ,
White Plains, New York

(From the New York Hospital and the Departments of Medicine and Psychiatry, Cornell University
Medical College)

IT IS our belief that lymphogranuloma venereum of the anorectal type is acquired in males by the deposition of the virus of the disease upon the perineal region, anus, or within the anal and rectal lumina. A similar mechanism may exist in the case of the female in whom, however, it is more difficult to obtain satisfactory details as to the probable site of deposition of the virus

Bensaude and Lambling¹ studied 158 cases of anorectal lymphogranuloma venereum in France, 78 of which were in males and 80 in females. They reported in 1936 that they had obtained a statement of coitus per anum in 80 per cent of the infected males. Bensaude and Lambling concluded that the disease in the male began in the rectal mucosa and traveled through the rectal wall ultimately involving all of the elements of the wall. It was regarded as evidence in support of this contention that 78 males showed concomitant stricture and active inflammation of the rectal mucosa. In the case of the female, Bensaude and Lambling were of the opinion that, owing to the intimate connection between the vaginal and perirectal tissues, the disease began in the latter tissues and spread inward through the rectal wall. According to that hypothesis, the rectal mucosa was the last of the elements of the rectal wall to be involved in the disease. In support it was claimed that of 80 women with stricture, only 12 showed accompanying active inflammation of the rectal mucosa. It would appear, therefore, that Bensaude and Lambling employed the relative frequency of the co-existence of proctitis and stricture to indicate the site of entry

of the virus of lymphogranuloma venereum into the rectal wall. A high ratio of proctitis to stricture indicated an extraluminal infection, a low ratio, an intraluminal infection.

Little definite information upon the site of entry of the virus was gained from a consideration of the presence of inguinal buboes in the infected individuals. Of 90 persons with concomitant proctitis and stricture only 24 showed past or present evidence of inguinal involvement.

Very recently additional evidence has been produced that lymphogranuloma venereum can be acquired by young female children solely by contact with an infected source. In March, 1939, Sonck² in Scandinavia, reported the occurrence of 5 cases of the disease in girls whose ages were respectively, 9, 4, 9, 8, and 7 years. In each instance the mother showed a positive Frei reaction and was passing blood and pus per anum. Three of the 5 children were sisters and slept in the same bed as the mother who, in addition to the active rectal disease, presented many discharging sinuses in the abdominal wall in the neighborhood of the colostomy opening. Three of the children, when first examined, had a concomitant stricture and proctitis, the latter being manifested by the passage of blood and pus per anum. In another child proctitis developed five months after the appearance of the stricture and in the 5th there was rectal ulceration without stricture.

The material reported in this paper has been taken from the files of the Lymphogranuloma Clinic of the New York Hospital, 169 consecutive cases of

lymphogranuloma venereum, all with positive Frei reactions, were considered and were subdivided into the following clinical entities

	Cases
(a) Anorectal manifestations alone	108
(b) Inguinal manifestations alone	50
(c) Anorectal and inguinal manifestations concurrently	4
(d) Esthiomene alone	3
(e) Latent disease—no manifestations	2
(f) Esthiomene and anorectal manifestations	1
(g) Pelvic and anorectal manifestations	1

Race and Sex Distribution

(a) Anorectal manifestations alone

	Total	White	Colored	Porto Rican	Red Indian
Men	53	45	4	3	1
Women	55	16	36	3	0

(b) Inguinal manifestations alone

	Total	White	Colored	Porto Rican
Men	46	33	10	3
Women	4	2	2	0

(c) Anorectal and inguinal manifestations concurrently

White men	3
Colored men	1

White males accounted for 42 per cent of this series of cases of anorectal lymphogranuloma venereum, they formed the largest individual group. It was probable that this preponderance over colored women (who are usually regarded as supplying the largest number of cases of anorectal lymphogranuloma venereum) was artificial and due to the type of clientele received at the New York Hospital.

(a) *Individuals Showing Anorectal Manifestations Alone*—In this clinical picture there was the passage of blood and pus per anum, frequent and small bowel movements, and occasionally tenesmus and abdominal pain. The proctoscopic picture was that of an acute or chronic inflammation of the lower bowel wall, in most instances a stricture was present. No significant difference between the 2 sexes was noted in the frequency of the concomitant occurrence of proctitis and stricture. In most, proc-

titis and stricture were both present. It was not possible, in any instance, to detect the presence of enlarged lymphatic glands in the pelvis.

(b) *Individuals Showing Inguinal Manifestations Alone*—Proctoscopic examination was made of these individuals on admission and at three or six monthly intervals thereafter. In none was there involvement of the bowel either at the time of the acute inguinal condition or at any period up to, in some instances, as long as fifteen years after the infection of the inguinal glands.

(c) *Individuals Showing Anorectal and Inguinal Manifestations Concurrently*—In each of the 4 cases examined the bowel involvement was in a very early stage with acute inflammation and ulceration of the anal and perianal tissues. It was felt that the purulent inguinal adenitis resulted from the infection in the perianal and anal areas.

Of the 114 cases of anorectal lymphogranuloma included in this study 53 were available for inquiry regarding their sexual habits. Fifteen of these were women. Twenty-four of the 38 men and 5 of the 15 women acknowledged having had passive rectal intercourse during the period that the lymphogranuloma infection probably occurred.

Circumstantial evidence indicates that a number of the men who denied having had rectal intercourse were not telling the truth. One, a taxicab driver, was impotent with his wife and admitted oral relations with men but denied rectal intercourse. Another man had been employed as an usher in a theater and acknowledged passive fellatio but denied rectal relations. Ten of the men were well acquainted with the practice of anal intercourse but denied that they had participated. The occupations of these men were as follows: a Pullman porter, a hospital porter, a waiter, a bookkeeper, a clerk, a mechanic in the navy, a handy man, a gas station attendant, a butcher, and a steel worker. The last 2 of this group were worthy of suspicion because one gave the unlikely story of having noticed symptoms of his disease shortly

after he had used some "dirty wet toilet paper" which he had picked up from the floor of a public toilet and the other indicated from his attitude and facial expression that he was not telling the truth.

One other man gave the story of having infected himself through the use of "bits of paper" picked up from the floor of a public toilet. His experience in giving plausible stories might have obtained for him the benefit of doubt had it not been for the statement of his wife that they had had sexual relations only once or twice in the previous three years and the further statement that her husband had recently been arrested in a subway toilet for having sexual relations with men.

Of the remaining 2 men who denied having had rectal intercourse one was a mechanic who took enemas for constipation and the other was a Porto Rican young man, twenty-two years old, who had already had a colostomy because of a lymphogranulomatous stricture. He had been given enemas in Porto Rico frequently by his mother since childhood. The same enema tube had been used with his 9 siblings, by his parents, and by 1 or 2 of the servants in the house.

Ten of the 15 women did not admit having had rectal intercourse. One of these acknowledged that she had had relations from the rear with her husband, but that penetration had been confined to the vagina. She had noticed that her husband had a yellowish discharge from his urethra. A Porto Rican woman who had been married, divorced, and married again, denied rectal relations but said she sometimes bled from the rectum following sexual relations, and that immediately after these relations she had a desire to move her bowels.

Of the remaining 8 women, 7 were Negro women and the other was a white married woman. She and 4 of the colored women had heard of rectal intercourse. Of the 3 colored women who did not admit knowledge of rectal intercourse, one had been twice married and was promiscuous in her sexual relations, another admitted she was promiscuous in her sexual relations, and the third gave the

story that she lived with a woman who had a vaginal discharge.

The proximity of the vaginal and anal orifices and the frequency of some form of vaginal discharge probably accounts for a large proportion of anorectal lymphogranuloma in women. Infection could be transferred to the rectal mucosa purely by the action of gravity and probably through the preliminary maneuvers of the male in effecting vaginal penetration.

From information obtained from the women included in this study it is probable that infection is often transmitted to the rectal mucosa through the careless use of douches and enema tubes. Four of the 10 women who denied rectal intercourse acknowledged that they gave themselves enemas immediately after vaginal douching, using the same apparatus with the exception of the nozzle. Moreover, a woman in giving herself an enema inserts the nozzle after passing it by the vaginal orifice.

Some physicians may have difficulty in getting a history of rectal intercourse in cases of anorectal lymphogranuloma and it may be desirable to comment upon the technic employed. One of the authors of this article is a psychiatrist who has had a number of years' experience in the study of psychosexual maladjustment. This experience was exceedingly helpful in dealing with patients who came primarily to be treated for a physical disease and who might resent an inquiry in which abnormal sexual relations were suggested.

In all cases it seemed desirable to conceal the fact that the interview was being conducted by a psychiatrist and no reference was made to sexual behavior until after a somewhat detailed and routine medical history had been obtained and the confidence of the patient had thus been secured. At first, circumstantial evidence was obtained, such as the occupation, the experience with women and the preference for men or women as social companions. Then the patient might be asked whether as a boy, other boys had pretended he was a girl or whether other

men teased him or whether men approached him for sexual purposes. The final specific information regarding passive rectal intercourse was usually the last obtained. With most of the patients it seemed advisable to conclude this part of the inquiry in one interview as the patient was in this way taken off guard and did not have an opportunity to elaborate an untruthful response.

The resistance on the part of men to acknowledge passive rectal intercourse is due, in large part, to the fact that among the group of sex variants and by men as a whole the passive rectal relationship is a mark of femininity. The man who thus submits himself is likely to be regarded with utmost contempt. The majority of such men are exceedingly insecure and feel defeated. Some of them actually wish they were women.

As a rule the women who have had rectal intercourse and who have acquired rectal lymphogranuloma have little desire to conceal their sexual habits. Often they have submitted to men under protest and the subsequent rectal infections make them communicative regarding the source of the infection.

Comment

In our series, the observation of Bensaude and Lambing that proctitis and rectal stricture do not frequently co-exist in women has not been confirmed. We feel, therefore, that one of the chief pillars of support of their hypothesis of a mode of production of anorectal lymphogranuloma venereum in women different from that in men is of doubtful strength. The case reports of Sonck already quoted show that anorectal lymphogranuloma venereum can be acquired by the female without the deposition of the virus intravaginally. An additional case report of Sonck (not quoted above) makes it clear that infection of the anorectal mucosa can be produced by anal intercourse with a lymphogranulomatous individual. It may be argued that, although the virus is deposited upon the mucosa it subsequently travels to the pelvic glands and invades the rectal wall from without. If

such were the case, one would expect to find palpable enlargement of the pelvic glands as occurs in individuals with primary syphilis of the rectum. One does not, however, encounter demonstrable pelvic adenopathy in anorectal lymphogranuloma venereum. The conclusion is inescapable that the anorectal mucosa is an excellent medium for the propagation of the virus of lymphogranuloma venereum.

The frequent history of anal intercourse in males who present no previous manifestations of lymphogranuloma venereum and the absence of anorectal symptoms as a sequel to the inguinal disease leaves little doubt that most cases of anorectal lymphogranuloma venereum in males are acquired by the deposition of the virus upon the perianal region, the anus, or within the anal and rectal lumina. It is also very probable that many cases of the disease in women arise in the same fashion.

Discussion

Dr David Bloom, New York City—Dr Grace, in expressing the opinion that the great majority of males affected with the rectal type of lymphogranuloma venereum acquire this disease by direct inoculation of the virus through passive pederasty, shares this belief with many French authors, like Rachet and Cachera, Ravaut, Caminopetros, and others. This assumption is based mainly on the admission of many males in their series that they practice passive pederasty. Thus, it seems to me, may perhaps mean only that these men belong to a certain stratum of population. To make it somewhat more convincing, the frequency of this mode of sexual practice should have been also investigated among males affected with the inguinal type of the disease and with chancroid and the figures compared with those found in males affected with the rectal type of the disease.

As to the other argument, namely, that very few of these rectal patients give a history or show signs of preceding inguinal bubo—this fact is true. But it has been explained satisfactorily and convincingly as follows: the patient who develops inguinal bubo is not likely to get rectal

involvement, for he is protected against the deeper penetration of the virus into the pelvis. For the bubo represents the battlefield of the virus with the organism, the latter being the victor. The cases of Kornblith, Oury and collaborators, Reichle and O'Connor, Cézary and collaborators, and of others, which demonstrate the development of pelvic and rectal disease in spite of the precedence of a typical inguinal bubo show that in some cases the virus is the victor over the glandular tissue and thus is able to advance unhampered deeper into the pelvis and toward the rectum. These thorough and detailed reports serve very well to enlighten us without any doubt about the mechanism of migration of the virus from the genitals to the rectum when it is not stopped by the inguinal lymph glands.

The third argument in favor of the intrarectal mode of inoculation in males was given by Lambing, namely, that in these patients, in contradistinction to females, there is a higher proportion of proctitis without stricture than with rectal stricture. This has been denied by Dr. Grace, and I agree with him. For also in the patients whom I have observed this difference between men and women has not been seen. Even in a patient with absolutely certain intrarectal inoculation it has been observed by Seneque that the virus behaves in the rectal tissues like in the inguinal region, namely, it starts with a tiny lesion in the mucosa then invades the anorectal glands of Gerota which suppurate, and thus facilitates ulceration of the mucosa and later the development of stricture.

Because of the above reflections the conception of Dr. Grace is unacceptable to me. Not because this mode of infection is impossible do I disagree. Such cases with absolutely certain intrarectal infection have been observed by others and myself. I disagree because this

theory seems to me not to be based on entirely convincing deductions.

How then are the majority of cases of rectal involvement in males explained in regard to the mechanism of infection?

It is true that the lymphatic circulation in men is different from that in women. In women the nearness of the rectum to the posterior vaginal wall and the direct lymphatic drainage of the vagina and the cervix to the deep pelvic glands explain easily the mechanism of development of rectal disease. This is not the fact in men in whom the lymphatics of the genital region drain mostly into the superficial inguinal glands. But it should be remembered that the glans penis, the sulcus coronae, and the corpus cavernosum have also lymphatics draining into the deep inguinal glands from which lymph vessels go to the iliac glands. Besides, there are also present—although few—lymphatics which lead directly into the deep pelvic glands. These anatomic conditions make it possible, therefore, for the virus to reach the pelvic glands and the rectum without affecting the superficial inguinal lymph glands. Another possibility of inoculation must be thought of, namely, that of the posterior urethra. Such cases have been reported by Mathewson. Many cases of rectal stricture in males have been observed by him, in which urethritis preceded the rectal involvement, and it is his belief that this mode of infection is to be blamed for many cases of rectal disease in males.

For all these reasons I share the opinion of Gatellier and Weiss who, at the French Congress of Surgery in 1934, have stated that the majority of cases of rectal involvement in men have acquired their infection, like women, by the genital inoculation of the virus which has migrated by the way of the lymphatics toward the perirectum and rectum.

HOW TO LOSE PATIENTS

Proper sanitary and sterile precautions should be synonymous with every doctor's office, but unfortunately this is not always the case. There is, of course, no excuse for this condition. Many patients have been repelled by the failure of the physician to observe the rules of ordinary cleanliness, both personal and in the use of instruments and dressings. These careless habits of the physician may represent an innate quality which is difficult to correct. The older physician will seldom recognize any necessity for reform along these lines, but the younger man should realize the danger involved in these undesirable habits and guard against the tendency of their accentuated expression as he grows older in practice.

Competition among physicians today is too acute to warrant a careless disregard for some of these seemingly unimportant details. In cities and towns where medical facilities are now concentrated, with a free choice among a number of competent physicians, the proper regard for some of these factors will account for the success of one man in contrast with the failure of another.

In building a practice today, the physician should not disregard the psychological factor, which may be determined by impressions gained from the surroundings in his own office.—Stanley R. Mauck, Exec. Sec., Columbus Acad. of Med., in *Ohio State M. J.*

Case Reports

CARCINOMA OF THE COLON OCCURRING IN A GIRL OF 13 YEARS

WILLIAM B RAWLS, M D, New York City

AN ITALIAN female, aged 12 years, 11 months was first seen November 19, 1937, when she complained of pain and soreness over the entire abdomen, anorexia, weakness, and loss of weight. Since May, 1937, she had noticed that, when engaged in violent exercise, there was moderate pain in the upper left quadrant which recurred at infrequent intervals and was unrelated to food intake. She continued to attend school and engaged in normal physical activities until the middle of August when she again complained of weakness and anorexia. The pain over the upper left quadrant was more frequent and there was a slight loss of weight. As on the previous occasion there was no nausea or vomiting and no blood in the stools. The symptoms gradually increased in severity and in November, 1937, there was constant pain and soreness over the entire abdomen, marked weakness, anorexia, mild nausea, and constipation. The weight had dropped from 86 to 74 pounds.

Physical Examination—Patient appeared acutely ill, emaciated, and dehydrated. The head, neck, and throat were negative. There were no palpable glands in the neck or axillae. The heart and lungs were normal. Abdomen there was considerable distention and tenderness over the entire abdomen although it was more marked over the upper left quadrant. The

abdomen had a doughy feeling. A mass about the size of a small orange was felt over the transverse colon close to the splenic flexure. No glands were palpable in the skin or other regions. The liver and spleen were normal.

Laboratory Examinations—Urinalysis acid, pale amber, albumin, sugar, and acetone negative, indican positive, rbc rare (Benzidine negative), 1-2 wbc per high power field, large amount of mucus, one hyaline cast, many squamous epithelial cells, few round epithelial cells, few cylindroids. Blood count rbc 4,530,000, hemoglobin 78 per cent, wbc 9,200, polymorphonuclears 55, lymphocytes 42, mononuclears and eosinophiles 0, basophiles 1, myelocytes 2. Schilling count segmented 37 stab 18, myelocytes 2, Schilling index 0.54 multiple index 8.64.

Röntgen-ray Examination (Dr Ramsay Spillman)—Examination of the chest, in P A and lateral projections, showed no evidence of disease. Films of the abdomen before any barium was given showed a stippled calcification in the left upper quadrant which was not confined to the limits of an apparently normal kidney shadow. This calcification was at the level of the second and third lumbar bodies with the

FIG 1 Calcification in left upper quadrant. It was shown by lateral projection to be well anterior to the vertebral column. It was not in either the kidney or the spleen.

FIG 2 Two attempts at barium enema failed to fill the colon beyond the splenic flexure. A small amount of barium was given by mouth and this film was made on the following day. This is an oblique, almost lateral, projection of the splenic flexure region. The involved colon is surrounded on all sides by the calcification.

FIG 3 Microscopic examination showing remnants of small glandlike structures and signet ring cells of the so-called mucinoid or colloid carcinoma

patient supine, and shifted only slightly with the patient standing. It was too low and too far medial to be in the region of the normal spleen, and no shadow of an enlarged spleen was found (see Fig 1).

Two barium enemas were given but no barium passed the splenic flexure. A small amount of barium was then given by mouth and exposure made twenty-four hours later. The barium from above formed a continuous shadow in the transverse and descending regions of the colon but the transverse colon for about an inch proximal to the splenic flexure showed considerable constriction and the calcification could be seen on all sides of this part of the colon. The colon appeared to run through the calcification as a stove pipe through a wall. There was considerable stenosis of the colon, though there was no dilatation on the proximal side (see Fig 2).

The age of the patient and the presence of calcification suggested a tuberculous process. An exploratory operation was advised and performed on December 6, 1937, by Dr Robert E. Brennan who made a preoperative diagnosis of malignancy.

Operative Procedure—A left rectus incision was made below the costal arch. A large quantity of serous fluid was evacuated. A hard, infiltrating mass presented itself, surrounding the splenic flexure, a portion of the transverse colon,

and involving the surrounding omentum. The anterior parietal peritoneum, small intestine, and pelvis were studded with small, hard nodules. The transverse colon was brought *in situ* proximal to the mass and a mushroom catheter inserted to overcome the partial obstruction. A small piece of the tumor mass was removed for histologic study and the abdomen was closed in the usual manner.

Pathologic Report (Dr Aaron S. Price)—The specimen consisted of a tumor nodule, measuring approximately 2 cm in diameter, which was firm and had a colloid-like appearance suggestive of malignancy.

Microscopic examination showed a nodule from the omentum which was densely infiltrated with mucinous exudate. Scattered through the material were remnants of small glandlike structures and some typical signet ring cells of the so-called mucinoid or colloid carcinoma, usually primary in the gastrointestinal tract. With a known mass of the lesion in the colon, the lesion was probably primary at that point (see Fig 3).

The patient made an uneventful recovery from the operation and left the hospital in about two weeks. She was then referred to Dr George T. Pack for roentgen-ray treatment and was admitted to Memorial Hospital on January 5, 1938, where she remained until February 20, 1938. During the stay in the hospital she re-

under which this process takes place. It does not occur in every case, even under conditions which look the most favorable. The laminations (in healing) may be in some way due to a successive deposition. Gradually the aneurysm may become filled even to the mouth and in this way permanent healing may be affected."

The outlook is certainly always grave in a fully developed aneurysm of the aorta and any form of medical treatment that may retard its progress and possibly lead to a cure is noteworthy. It is surprising, however, that the current modern textbooks on medicine either fail to mention venesection for aneurysm or do so only to point out its limitations.

Edgar V Allen² in *Musser's Internal Medicine*, states "There is no known medical treatment for aneurysm, except restricted activity and prescribing of a diet low in calories, in an attempt to reduce arterial pressure." Meakins³ in his textbook *Practice of Medicine*, states "The second line of attack is the hope of preventing the local tumor from further enlarging, and at the same time promote local thrombosis. The essentials of this treatment are rest and a concentrated diet." He does not mention venesection.

Malcolm Goodridge⁵ in *Cecil's Textbook of Medicine*, states "The various measures to increase the coagulability of the blood, which have been suggested, such as frequent small bleedings—are of little value."

Henry A Christian⁶ in *Osler's Principles and Practice of Medicine*, mentions that "Pressure on veins causing engorgement, particularly of the head and arms, sometimes is relieved promptly by free venesection, and, at any time in attacks of dyspnea with lividity, bleeding may be done with great benefit."

Paul White⁷ in his textbook, *Heart Disease*, makes no mention of venesection for aneurysm. All of these authors mention the fact that bed rest, restricted diet, and judicious antiluetic treatment are valuable in the management of patients suffering from aneurysm.

Case Report

F G, an Italian male 57 years of age, sought medical attention on October 8, 1937, because of the presence of swelling in the upper chest, cough, and palpitation. These symptoms were first noticed during the summer of 1932, and became pronounced during the summer of 1936. The family history was irrelevant and the past history disclosed the fact that the patient had indulged in many heavy weight-lifting feats. Luetic infection was denied.

Examination revealed a short, stocky, well-nourished very muscular adult male with a very good hemic component. A pulsating bilobular mass approximately 9 cm in diameter and 6 cm deep was present just below the supra-sternal notch. The overlying skin was thin and discolored. This mass pulsated forcefully and rupture seemed imminent and unavoidable. Around its base a systolic murmur was heard. The left border of the heart was 11 cm in the fifth left interspace and right border 3 cm in the fourth right interspace. At the apex the first

ceived high voltage x-ray cycle to two abdominal ports 150 r daily alternating until a total dose of 2,100 r by 2 had been administered. She also received two transfusions of unmodified blood, 300 cc each. The slides previously made by Dr. Price were reviewed by Dr. James Ewing who concurred in the diagnosis of gelatinous carcinoma of intestinal origin.

A barium enema revealed complete obstruction at the upper end of the descending colon. A thin water barium mixture was injected retrograde through the colostomy, and there seemed to be a narrowing of the splenic flexure of the colon with, apparently, a complete obstruction of the upper descending colon.

The patient was discharged on February 20 as unimproved but returned to the clinic for follow-up. She continued to have considerable abdominal pain and discomfort after eating and continued to lose weight. On April 20, 700 cc of blood-tinged fluid was withdrawn from the abdomen. Later examination revealed a large mass in the lower right abdomen, one above the pubis, and a third, close to the opening of the colostomy. The liver was enlarged. The patient continued to lose weight and died at home on May 24, 1938. Postmortem examination was not made.

Discussion

Carcinoma of the colon occurring at this age is extremely rare. Pack and LeFevre¹ in review-

ing 16,565 cases of malignant diseases admitted to Memorial Hospital from January 1, 1917, to January 1, 1929, found 107 cases of carcinoma of the colon, the youngest patient 23 years old. Wainwright² in 1925 reported the case of a girl of 11 years and, in an extensive search of the literature, found only 6 cases of carcinoma above the sigmoid in patients under 16 years of age. Warthin,³ in 2,000 autopsies on patients with malignant disease, found 195 cases under 30 years of age but only 2 of them involved the colon. The ages were 18 and 24. Miller,⁴ reporting 129 cases of carcinoma of the colon found only one patient 17 years of age. Plehn⁵ observed a case of carcinoma of the cecum in a girl of 9 years, confirmed by roentgen ray operative, and histologic findings. Carcinoma of other abdominal viscera occurs much more frequently and at an earlier age than carcinoma of the colon.

ANEURYSM OF THE AORTA

Report of a Case with Apparent Complete Recession

EUGENE R. MARZULLO, M.D., Brooklyn, New York

(From the Department of Medicine, Long Island College Hospital, Brooklyn)

THIS case of aneurysm of the aorta is reported because of its apparent complete recession. Interest may be accentuated by the fact that, venesection, a part of the treatment used, was a well-recognized method of treatment in the eighteenth century. The combination of rest, low diet, and frequent bleedings was known as the Valsalva method of treatment of aneurysm. Morgagni¹ described it as follows: "When as much blood as was requisite was withdrawn (by repeated bleedings), he (Valsalva) ordered a progressive diminution of food and drink until the quantity was reduced to a determined weight of ailment and water. Having so enfeebled the patient that he could scarcely raise his head from bed, on which he was ordered to lie from the beginning, the quantity of ailment was cautiously increased." This procedure was the popular method of treatment for aneurysm in the eighteenth century and it continued to enjoy popularity throughout the greater part of the nineteenth century. In 1848, Dr. Thomas

Watson, in his book, *Lectures on the Principles and Practice of Physic*, and in 1884, Austin Flint in *Flint's Practice of Medicine*, described it and commented favorably upon its value. In the latter part of the nineteenth century, however, this method gained disrepute. It became unpopular because it was considered drastic and in some instances more intolerable than the aneurysm. Sudden death from rupture of the aneurysm or from a complication such as heart failure in the course of treatment utilizing venesection was the probable final cause for its renunciation and abandonment. But again in 1908, Osler² in *Osler's Modern Medicine*, spoke highly of venesection for aneurysm. He mentions the fact that cures have been reported in the literature and that healing takes place by one of two methods, connective tissue formation and thrombosis. He states: "The second great element in the repair of an aneurysm is thrombosis, the deposit of laminated fibrin in the sac. We are as yet ignorant of the precise conditions

FIG 1

under which this process takes place. It does not occur in every case, even under conditions which look the most favorable. The laminations (in healing) may be in some way due to a successive deposition. Gradually the aneurysm may become filled even to the mouth and in this way permanent healing may be affected."

The outlook is certainly always grave in a fully developed aneurysm of the aorta and any form of medical treatment that may retard its progress and possibly lead to a cure is noteworthy. It is surprising, however, that the current modern textbooks on medicine either fail to mention venesection for aneurysm or do so only to point out its limitations.

Edgar V. Allen³ in *Musser's Internal Medicine*, states "There is no known medical treatment for aneurysm, except restricted activity and prescribing of a diet low in calories, in an attempt to reduce arterial pressure." Meakins⁴ in his textbook *Practice of Medicine*, states "The second line of attack is the hope of preventing the local tumor from further enlarging, and at the same time promote local thrombosis. The essentials of this treatment are rest and a concentrated diet." He does not mention venesection.

Malcolm Goodridge⁵ in *Cecil's Textbook of Medicine*, states "The various measures to increase the coagulability of the blood, which have been suggested, such as frequent small bleedings—are of little value."

Henry A. Christian⁶ in *Osler's Principles and Practice of Medicine*, mentions that "Pressure on veins causing engorgement, particularly of the head and arms, sometimes is relieved promptly by free venesection, and, at any time in attacks of dyspnea with lividity, bleeding may be done with great benefit."

Paul White⁷ in his textbook, *Heart Disease*, makes no mention of venesection for aneurysm. All of these authors mention the fact that bed rest, restricted diet, and judicious antiluetic treatment are valuable in the management of patients suffering from aneurysm.

Case Report

F. G., an Italian male 57 years of age, sought medical attention on October 8, 1937, because of the presence of swelling in the upper chest, cough, and palpitation. These symptoms were first noticed during the summer of 1932, and became pronounced during the summer of 1936. The family history was irrelevant and the past history disclosed the fact that the patient had indulged in many heavy weight-lifting feats. Luetic infection was denied.

Examination revealed a short, stocky, well-nourished, very muscular adult male with a very good hemic component. A pulsating bilobular mass approximately 9 cm in diameter and 6 cm deep was present just below the suprasternal notch. The overlying skin was thin and discolored. This mass pulsated forcefully and rupture seemed imminent and unavoidable. Around its base a systolic murmur was heard. The left border of the heart was 11 cm in the fifth left interspace and right border 3 cm in the fourth right interspace. At the apex the first

FIG 2

FIG 3

sound was short and faint. There were no murmurs at the apex. The second sound at the base was audible. The lungs were clear. The liver and spleen were not palpable and the lower extremities showed no edema.

The blood pressure, right arm was 90/58 and the left arm 120/70.

The blood Wassermann and the spinal fluid Wassermann were negative.

The urine was essentially normal as was also the blood chemistry.

Fluoroscopic and x-ray examination of the chest on October 27, 1937, revealed a moderately large aneurysm of the ascending portion of the aortic arch.

Comment

The Valsalva method of treatment for aneurysm, referred to before, was undoubtedly applicable to aneurysm the result of syphilis. In this reported case the aneurysm involved the arch of the aorta and as such its etiology was considered to be luetic in spite of repeatedly negative serology. Antiluetic treatment was not instituted.

The aneurysm had eroded the manubrium. Its external pulsation was so forceful that rupture seemed imminent and venesection was performed to avoid its occurrence. Immediate and striking relief resulted and I was encouraged to repeat it in an effort to establish a cure by thrombosis, because I have observed, that after an acute loss of blood there sometimes occurs a marked increase in the blood platelets and a diminution in the bleeding time and clotting time.

Venesection and phenylhydrazine were primarily used in order to produce anemia so as to diminish the total blood volume, it having been reported by Rowntree, Brown, and Roth⁴ that the mean total blood volume in secondary anemia was as low as 33 per cent less than the mean for normal persons.

The patient was kept in bed for a month on a diet low in calories. The chart on treatment reveals that venesection, 500 cc. at a time, was done over a period of two months. It is to be noted (see chart) that with this treatment there was a reduction in the blood count, the bleeding time was reduced to fifteen seconds, the clotting time to one minute, and the blood platelets increased to 680,000 per cm.

Clinically, the first symptom to improve and disappear was the abnormal pulsation. The cough and the hoarseness improved and disappeared within the first two weeks of treatment. The aneurysm became reduced in size appreciably, in less than three weeks after five venesections of 500 cc. of blood each. It disappeared entirely at the end of seven months.

As time went on the patient was followed by fluoroscopic examination and when no further abnormal pulsation of the aorta was apparent, the blood count was allowed to return to normal. At present the patient has no symptoms and he is pursuing normal activities with no evidence of aneurysm by fluoroscopic examination.

In the patient referred to in this report, the

diminished blood volume, the diminished clotting time, and the high platelet count were conducive to healing of the aneurysm by the deposition of fibrin and by thrombosis in the aneurysmal sac

Conclusion

1 A case of aneurysm of the aorta with apparent cure is reported

2 Bed rest, regulated diet, venesection, and phenylhydrazine therapy are advocated for the treatment of aneurysm.

3 The literature on venesection for aneurysm is reviewed

Legislative News

Bulletin No 3

(January 24, 1940)

New Bills Introduced

SENATE INT 475—Ryan, Assembly Int 466—Devany, creates a temporary commission to study and recommend measures for improving facilities and care of youth and appropriates \$10,000. Referred to the Finance Committee in the Senate and the Ways and Means Committee in the Assembly.

COMMENT Mr Ryan proposes the creation of a temporary State commission consisting of five members appointed by the Governor and five legislators, in addition to the Commissioners of Health, Education, Agriculture, Correction, Mental Hygiene, Labor, and Social Welfare, for the purpose of studying all State, Federal, and local laws relating to youth and to make recommendations and propose such legislation as it may deem proper, with special reference to unemployment, relief, health, guidance, education, leisure time activities, and crime prevention aids.

Senate Int 484—Wicks, permits counties and cities to establish cancer clinics, the State to grant a sum not exceeding one-half the actual cost of maintenance not in excess of \$7,500 a year for each clinic and \$5,000 toward installation and equipment. Referred to the Health Committee.

COMMENT Senator Wicks informs us that he introduced this bill after discussing with physicians in his county—Ulster—the means and methods available to them for early diagnosis and treatment.

Senate Int 508—Desmond, Assembly Int 695—Vincent, defines the practice of radiology as practice by any person making examinations of the human body by use of x-rays or by means of fluoroscopic exhibition or by shadows registered with photographic material and use of x-rays, except one employed under supervision of another who is duly qualified to practice medicine, purpose being to prohibit such practice by any person other than one licensed to practice medicine, dentistry, or chiropody. Referred to the Education Committees.

COMMENT This bill has been prepared by the radiologists and we are informed it does not contain the objectionable features of similar bills that were defeated last year. It specifically and rightly provides that radiology shall be a part of the practice of medicine and its practice regulated under the medical law.

Senate Int 510—Feinberg, Assembly Int 476—Steingut, makes mandatory, instead of permissive, the licensing by Industrial Commissioner of workmen's compensation medical bureaus and laboratories upon recommendation of County Medical Society, and provides that bureaus may be supervised as well as operated by qualified physicians, medical bureau may appeal to Industrial Commissioner if County Society or board fails to recommend establishment of such bureau or laboratory. Referred to the Labor Committees.

Assembly Int 461—Austin, requires New York City Education Board to establish child guidance bureau with staff of psychiatrists, psychologists,

and social workers, diagnosis and treatment of child are not to be provided if parent or guardian objects. Referred to the Education Committee.

Assembly Int 469—Goldstein, establishes a state-wide plan of public medicine and reorganizes the Health Department, establishes therein four new divisions, medical, dental, nursing care, and pharmacy, with jurisdiction over health functions of various departments and other activities relative thereto, makes salary of Commissioner \$15,000, provides for three deputies at \$12,000, and appropriates \$500,000. Referred to the Ways and Means Committee.

COMMENT Mr Goldstein had this bill before the Legislature last year. Its principal feature is that it would collect all activities that relate to health and the practice of medicine from the various State Departments, as Education, Labor, Agriculture, etc., and combine them under the Commissioner of Health.

Assembly Int 470—Goldstein, permits the State to operate and conduct lotteries, net proceeds of which shall be devoted to carrying out long-range health program to safeguard health of people and distribute public medicines. Referred to the Judiciary Committee and by it to the Attorney General for opinion.

Assembly Int 477—Vincent, permits sale of narcotic drugs by certain physicians or surgeons. Referred to the Health Committee.

COMMENT Same as Senate Int 240—Young, reported in Bulletin No 2.

Assembly Int 499—Gans, relative to reports of physicians in workmen's compensation cases. Referred to the Labor Committee.

COMMENT Same as Senate Int 314—Condon, reported in Bulletin No 2.

Assembly Int 619—Peterson, requires a peace officer, on arrest, to take before a physician designated by a Medical Society, for examination, a motor vehicle or cycle operator whom the officer believes to be intoxicated. Referred to the Motor Vehicles Committee.

COMMENT Mr Peterson has had this bill before the Legislature the last two years and we supported it in principle. Some question was raised as to whether the tests suggested in the bill are adequate and whether a physician would have a legal right to perform them.

Assembly Int 646—Dollinger, provides for care and assistance by city and county welfare districts to needy tuberculous persons and their dependents, reimbursement therefor to be made by the State Social Welfare Department in whole or in part, persons receiving such aid cannot receive old-age assistance or dependent child aid. Referred to the Relief and Welfare Committee.

COMMENT In this bill the definition of "tuberculous" is: "A person shall be considered tuberculous who has undergone treatment for tuberculosis and has not been an apparently arrested case for five consecutive years. Classification of the tuberculous condition within the provisions of this definition shall be determined

according to standards adopted by the State Department of Health" A person who may be eligible for financial assistance "(1) Is tuberculous as defined above, (2) Has resided in the State for at least one year immediately preceding the institution of treatment for tuberculosis either as a new or relapsed case, (3) Has not sufficient income or other resources to provide a reasonable subsistence compatible with decency and health, and has no children or other person able to support him and responsible under the provisions of this chapter for his support, (4) Has not declined to accept employment under reasonable conditions or to receive training medical care, or other assistance which might reasonably be expected to improve his condition, (5) Is not an inmate of any public institution or of any private institution to which an admission fee has been paid or transfer of property has been made, (6) Has not made a voluntary assignment or transfer of property for the purpose of qualifying for such assistance, (7) Is not, because of his physical or mental condition, in need of continued institutional care" The assistance may be provided "in the person's own home or room" Temporary care in a hospital or sanitarium may be provided with the approval of the State De-

partment. Under rules and regulations to be established by the State Department, assistance may be granted to eligible applicants who are receiving training or education or who are waiting for employment The amount and nature of the assistance to be granted and the manner of providing it shall be determined by the public welfare officer The cost of furnishing such assistance is to be borne by the public welfare districts subject to reimbursement by the State to the extent of one-half

Bulletin No 4

(January 31, 1940)

Bills Introduced

SENATE INT 599—Condon, Assembly Int. 833—Armstrong, provides that the amount of the fee which an employer or carrier must pay a physician of injured employee in a workmen's compensation case shall be fixed by the industrial board instead of the commissioner Referred to the Labor Committees

COMMENT This amendment has been recommended by the Department of Labor and approved by our Committee on Workmen's Compensation.

Senate Int. 709—Condon, includes in workmen's compensation coverage any incorporated volunteer fire companies rendering fire protection service on contract basis, who elect to be so covered by resolution of board of directors or trustees after notice to members Referred to the Labor Committee.

COMMENT Reported as a matter of information.

Senate Int. 765—Gutman, authorizes education boards to employ psychologists, visiting teachers, and social workers with training in psychiatric social service. Referred to the Education Committee.

COMMENT Adds to the Education Law which provides for the employment of medical inspectors that boards may employ psychologists and visiting teachers or social workers with training in psychiatric social service. Mr Gutman, when an Assemblyman last year, had this bill before the Assembly It was never reported out by the Education Committee and was disapproved by us

Senate Int 792—Page, Assembly Int. 878—Todd, provides that after July 1, 1941, instead of 1940, it shall be unlawful to practice nursing without being duly licensed and registered. Referred to the Education Committees

COMMENT The Department of Education reports that it will not be able to examine and license all nurses who are applying under the new law by July 1, 1940, as the law requires, therefore this petition for extension of a year

Assembly Int. 981—Peterson, provides for the regulation of the practice of chiropractic under supervision of the Education Department. Referred to the Education Committee.

COMMENT This bill is almost identical with the one carried by Mr Peterson in 1936, 1938, and 1939 It provides for a special examining board of five members, appointed by the Regents, composed of chiropractors who shall have one of the three qualifications—either a graduate of a four-year-school course and three years of practice, of a three-year-school course and ten years of practice, or a two-year-school course and fifteen years of practice in this state. *No provision is made for examining or licensing members of the board*, and since no chiropractors have been licensed in this state, it is to be assumed that the members of the board would be licensed by waiver The board shall have charge of preparation and grading of examination papers and shall license to practice any person who shall pass a *special examination* in the principles and practice of chiropractic and is (a) a graduate after resident course of twenty-four months in a school or college teaching chiropractic and shall have been practicing chiropractic in this state for six months, (b) a graduate after a resident course of eighteen months in a school or college teaching chiropractic and shall have been engaged in the practice of chiropractic for three years in this state, (c) after a resident course of twelve months and ten years of practice in this state.

The schools referred to above must be schools

or colleges of chiropractic acceptable to the board (of chiropractors, not Board of Regents) and the course of study include the subjects of anatomy, physiology, symptomatology, hygiene and public health, and the principles of chiropractic. The Department of Education has approved of no school or college of chiropractic.

If the *chiropractic board approve*, the Department of Education may waive the examination of an applicant for license who has been duly licensed or registered as a practitioner of chiropractic in any other state of the United States having registration or license requirements equal to those provided in this article.

For the future the applicants for examination must be graduates of a high school (after 1943 one year's college study may be required) and subsequently must graduate from a school or college teaching chiropractic which possesses apparatus, equipment, and resources of at least \$50,000 and six full-time instructors. The course of instruction shall cover four school years of not less than eight months each including biology, anatomy, histology, and embryology, hygiene and public health, bacteriology, physiology, biological chemistry, including dietetics, symptomatology, pathology, chiropractic analysis, x-ray as it relates to chiropractic analysis, and the principles and practices of chiropractic.

Some of our objections to the bill are (1) no provision is made for the licensure by examination of chiropractors to be appointed to the board, (2) no separate examining board is justified, (3) educational requirements are reduced in that preliminary education requires only a high-school course, while physicians and osteopaths are required to offer a high-school course and, in addition, a two-year pre-medical college course, (4) under the waiver provisions it would be easy for every person practicing chiropractic in the state today to secure a license, in spite of the fact that they do not have the basic educational qualifications.

If this bill were to be enacted into law the state would betray the trust the public has reposed in it for the licensure of adequately-trained persons for the care of the sick.

Assembly Int 1005—Wagner, creates in the Health Department a consumers' bureau for registration advertising control, analysis, scientific research, education, publicity and regulation of manufacture and sale of drugs, cosmetics, or health devices to prevent adulteration or misrepresentation. Referred to the Ways and Means Committee.

COMMENT Mr Wagner sponsored this bill last year.

Resolutions Introduced

By Mr Ives That at 12 o'clock noon, February 6, the Assembly nominate a candidate for the office of Regent in place of Grant C Madill, M D Ogdensburg, whose term is to expire. Adopted.

By Mr Ives That the Senate and Assembly meet in joint session at 12 o'clock noon, February 7, for the purpose of comparing nominations for the office of Regent in place of Grant C Madill, M D, whose term is to expire. Adopted in both Houses.

STORAGE OF BLOOD FOR TRANSFUSIONS SHOULD BE LIMITED TO TEN DAYS

A limit of between five and ten days for the use of blood for transfusion after it has been stored appears to be a safe restriction, due to the less satisfactory or even dangerous results which may follow the use of older blood, the *Journal of the American Medical Association* recommends in an editorial.

"The obvious advantages of storing blood for transfusion have led to the adoption of 'blood banks' by many large hospitals throughout the country," the editorial points out. "With regard to results of transfusion, it has been found that there is no difference in the incidence of untoward reactions provided the blood has not been kept too long.

"Investigations indicate that blood more than from a week to ten days old is not equivalent to fresh blood. Indeed, with blood that is too old

there is even some danger of blood in the urine and serious symptoms such as are known to result from the transfusion of incompatible blood.

"When the available data are taken into consideration, it is evident that the transfusion of preserved blood has acquired an important role. This is a great change in attitude from the opinion held less than two decades ago, when the transfusion of citrated blood even when fresh was looked at askance. However, there are definite limitations to the use of stored blood which should be taken into account. Pending further investigation, a safe limit to set for the use of such blood would be between five and ten days. Perhaps by improving the method of storing blood it may be possible to extend the time limit."

Medical News

The American Health Program*

NATHAN B VAN ETEN, M D

President-elect, American Medical Association

ACTING under the authority of the House of Delegates at the St Louis session, the Trustees recently wrote a new eight-point platform upon which American Medicine stands for objective realization of the desires of 116,000 physicians

Platform of the American Medical Association

The American Medical Association advocates

1 The establishment of an agency of federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy

2 The allotment of such funds as the Congress may make available to any state in actual need for the prevention of disease, the promotion of health, and the care of the sick on proof of such need.

3 The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility

4 The development of a mechanism for meeting the needs of expansion of preventive medical services with local determination of needs and local control of administration.

5 The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration.

6 In the extension of medical services to all the people, the utmost utilization of qualified medical and hospital facilities already established

7 The continued development of the private practice of medicine, subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability

8 Expansion of public health and medical services consistent with the American system of democracy

The essentials of this new platform of the American Medical Association are coordination of government health functions, governmental provision of funds for disease prevention and relief of uncared for sickness on proof of need, development of local responsibility for local demand and local control of administration, and encouragement of the private practice of medicine as far as possible in harmony with maintenance of a good quality of medical care.

In 1875 the American Medical Association asked for a Secretary of Health in the Cabinet of the President and has timidly restated its desire at various sessions of the House of Delegates—after which the delegates went home to practice medicine and forgot about it. If physicians really want a national health department they must step down from their dignified pedestals

and fight for it with weapons which legislators understand. These weapons are the votes of local electorates

The medical profession has been reviled as static, reactionary, and selfish. Of course, these accusations are untrue, but they will have wide belief unless physicians will realize the necessity of asserting themselves in their home localities and demand local support for their ideals

It is a serious reflection upon the virility of the medical profession that it seems to be necessary for political theorists to propagandize regimentation of medical service in order to arouse the physicians of this country to action

Coordination of all federal health agencies except those of the Army and Navy seems a logical thing to do. The health of our people should be the honest concern of the chief executive. And the health authority should be a member of his Cabinet

I would like to see a new national department to be known as the Department of Health headed by a secretary who must have had a medical education and be licensed to practice medicine. I would like this new department to include the following bureaus

- 1 Public health
- 2 Infancy and maternal welfare to be transferred from the Department of Labor
- 3 Rehabilitation of veterans
- 4 Research.
- 5 Licensure
- 6 Care of indigents
- 7 And other divisions to care for all other health responsibilities, fusing all departments into one less expensive to operate and eliminating the confusion of overlapping and duplication.

I believe the President should have the benefit of scientific advice in health and hygiene within his official family

The Declaration of Independence provided for governmental protection of life, liberty, and the pursuit of happiness. Jefferson must have thought of the health of the people as a concern of government

Owen D Young's group has recently called upon the government to take an active interest in the health of youth.

Defense against disease is quite as important as defense against the ideas and domination of foreign enemies

It seems to me to be timely to drop complicated and slipshod methods and attack the problem courageously and efficiently

Infancy and maternal welfare developed in the Department of Labor in response to a wide outcry against child labor. Its objective has been largely realized and now requires a wider and more general type of direction.

Rehabilitation of veterans, developed with well-known administration scandal, under a stimulated emotional campaign is now well es-

* Delivered before the Medical Society of the County of Queens January 30 1940

tablished—hospitals are widespread and may well have a broader significance with the passing of time under a Department of Health.

Appropriations for research are now vested in the bureaus of Public Health and in appointed committees. I believe that the value of such work would be greatly enhanced if these studies were coordinated in a Department of Health, where voluntary agencies, such as medical schools, voluntary hospitals, and philanthropic foundations could cooperate in directly helpful service for the information of the government.

The National Board of Medical Examiners could very well fit into a function of a national health department.

Medical care of indigency looms as one of the most important functions of government. A concert between local agencies through some new type of local, state, and national machinery could well be headed in a national health department.

The migrating indigent is one of those for whom no local agency is willing to assume the responsibility. They are pushed from state to state and travel from one seasonal employment to another.

No health insurance scheme can take care of such people who can make no regular contribution to any compulsory or government financing. Their care must be centralized. Would there be a better place for this work than in a national health department?

It would seem to be ideal to choose a career man to head this department. Some one who has been developed through the present department of Public Health or through service in some of the state administrations.

Examination of the current personnel in the various states shows a real need for more competent health officers.

Service in the various fields of public health should be carried on by career persons who should be developed through special postgraduate training beyond the ordinary undergraduate course in medicine.

Although it must always be borne in mind that a period of private practice seems to be necessary for understanding intimate personal medical problems, there is reason to feel that those who are to direct public health administration should be specially trained in the science of administration before entering such a field. Too often the health officer is merely a political appointee because he has influential friends rather than because he knows anything about the duties of the office. He should also be made conscious of the fact that he is only an administrator and not a practitioner of medicine.

The public consequence of private practice may need government umpiring, but government participation in private practice must not be tolerated.

I believe that the Secretary of Health should be a physician who has had enough experience in the practice of medicine to know the point of view of the patient as well as that of the physician.

He should not be a political theorist who can not know medical care of the sick because he has never practiced it.

There is evidence of a concerted drive for a general service to the sick, both preventive and curative, supported by taxation and under government control.

There is frequent reiteration of a desire for free medical care, patterned after free public education—all doctors salaried by the state—a complete system for state medicine. There seems to be no limit to the belief that the public purse will be able to pay for it, even in the presence of evidence that state education is already too costly for the public pocket. This belief continues regardless of the fact that school budgets are now the subject of acrimonious debate and regardless of the mounting national deficit.

In the State of New York last year state education absorbed 45 per cent of the state budget of \$385,000,000. State education takes care of people from the ages five to twenty-one only, while state medicine would involve the care of people from before birth to interment.

Prohibitive cost means nothing to some political theorists.

A new program must provide something better and simpler than these excursions into Utopia.

Unless we are ready to accept complete totalitarianism I believe that an American Health Program should operate from the periphery toward the center.

I believe that needs for help should be discovered in the smallest political subdivision such as the school district, then referred to the town ship, the county, the state, the federal authority in that order, and that the federal authority should be called upon as infrequently as possible.

I believe that medical service to the economic indigent is the problem of the taxpayer. The economic indigent may be defined as one who is unable to provide the necessities of life for himself and his family.

I believe that medical service to the medical indigent is the problem of the taxpayer. The medical indigent may be defined as one who cannot pay for medical care without sacrificing the necessities of life for himself and his family.

I believe that medical service to these two classes of people should be administered by the medical profession and that the physicians who do this work should be paid by the taxpayer.

I believe that medical service to other people of low income who are able to pay for ordinary but not for catastrophic illnesses should be shared by the medical profession and the taxpayer. The medical profession and the taxpayer should provide such needed medical service in tax-supported institutions either free or at minimum rates.

I believe that new mechanisms for caring for the health needs of the people involving all political subdivisions from the locality to the federal government should be developed no faster than administrative personnel can be sufficiently trained to be effective.

I believe that preventive medicine although largely a public health problem involving the control of communicable disease should be promoted by all practicing physicians upon whom should be imposed definite civic responsibility.

I believe that every effort should be made to provide for the average man so that he can prepare for emergencies without throwing himself upon the sources of charity.

I believe that hudgeting for sickness through insurance providing cash indemnity should be encouraged—as well as insurance against the cost of hospitalization—but that these two forms of insurance should be separate projects.

Compulsory systems of sickness insurance as now operating do not take care of indigents and are only interested in workers who pay for insurance of this type through payroll deductions.

I believe that the sentiments of groups of religionists who object to compulsory medical care through insurance or otherwise should be respected so long as their beliefs do not jeopardize the public health through neglect of ordinary health precautions for themselves or the community.

Neither creed nor race nor color should deprive any American of the benefits of the best of clinical medicine, but the manner of its delivery should evolve from simple formulae. The formulae should grow from the needs of the people as recognized by the family physician, the public health nurse, and local welfare workers.

The formulae should grow into workable being in an orderly way. This requires a period of time, for short steps before long strides must be taken. Much laboratory work must be done, as recognized by the President in his recent proposal to build small hospitals in regions where they are needed. This proposal is in harmony with the new platform of the American Medical Association.

It is a sane alternative to the extravagances of the proposed Wagner Health Act. It is a stimulant to local initiative to operate a facility erected by the government for the benefit of the locality.

It is also in harmony with the President's private statement on more than one occasion that he is opposed to any extensions of state medicine that can be avoided.

It is an immediate forward step toward correcting faulty distribution of medical facilities and may prove as attractive as are many hospitals to young physicians who may be seeking new locations.

The memory of an internship in a hospital furnishing every convenient facility is often disturbing to a young doctor's response to calls to country practices where he must be self-dependent.

It is to be hoped that these new hospitals will be placed in response to well-established local needs.

At the invitation of the President, committees from the American Hospital Association, from the Catholic Hospital Association, from the Protestant Hospital Association, and from the American Medical Association met the President at the White House early in January.

The committee reports that the President seems to be opposed to the enactment of the Wagner bill and apparently intends to propose to Congress that a sum approximating \$10,000,000 be appropriated for the purpose of building small hospitals in places where there appears to be great need of hospital facilities. This project was subsequently embodied in the President's message to Congress on January 30. Under the plan proposed, the federal government will build the hospitals, but the community, with or without state aid, will be required to maintain these institutions. The President stated that such hospitals when built will not be placed in undue competition with other hospitals. There was little discussion of details at the conference, though some felt that there should have been more such discussion since the practicalities of the situation seemed to demand it.

Following a discussion participated in by the committee representing the American, the Catholic, and the Protestant hospital associations and the American Medical Association, the following points were left with the President as representing their joint conclusions:

- 1 Hospitals to be built only where need can be shown. Advisory consultation in the determination of such need to be given by the state medical and hospital associations, the state health department and the county judges or officials of the counties in which such hospital services are proposed.

- 2 Size of hospital to be commensurate with the needs of the community and the ability of the latter to support it.

- 3 Means for the maintenance and upkeep of such hospitals rank in importance equal to that of construction.

- 4 Since the important objective of the program is the service it can render, hospital construction and administration, equipment, staff, and personnel should meet the standards which the American Medical Association, the American College of Surgeons, and the Hospital Associations regard as minimal for rendering such service in the various localities. Where needed, since highly specialized facilities and personnel cannot be made available in all places, affiliation with larger hospitals or hospital centers to be had to the end that highly specialized services, diagnostic and therapeutic, be made available to all.

- 5 Maintenance of a standard of professional and hospital service that will keep it efficient and prove attractive to qualified men and women as a career.

- 6 Utilization of existing facilities where possible. Under no circumstances should the program be allowed to develop into competition with the voluntary hospitals, but should rather foster cooperation between the two groups.

- 7 Many small communities can be better served by the utilization of bed vacancies in available existing institutions than by the construction of new hospitals, transportation, and per diem expense to be borne by federal, state, and/or county funds. Where state and/or county funds cannot be provided, such expense to be met by federal grants-in-aid to, and to be dispensed by, local agencies.

Ambulance service and good roads will permit this type of service to operate safely, efficiently, and economically in communities not financially able to support a hospital.

The President's proposal should have the hearty support of all physicians and public health workers. The President inspires us to travel the road to the future. His action indicates a belief that it is untimely that radical changes in national medical care should be precipitated while catastrophic clouds hang over our own nation and while the map of the world is being remade and a peaceful federation of nations seems impossible.

Although many of us were officers in the war twenty years ago, and some of us are now reserve officers, and all of us desire peace more than anything else, we are ready to take our places in support of the nation if the real emergency arises.

Supporting this sentiment the American Medical Association has already offered all of its or-

ganizational resources to the government and is ready to cooperate to the limit of its ability.

The American Health Program has been writing itself for one hundred and eighty-eight years since Benjamin Franklin opened the first hospital in America in 1752.

The American Medical Association has been motorizing this program for the last ninety-four

years cherishing an ambition not only to conserve all of the verities and values of this medical service evolution, but the projection of them into new objectives for the delivery of better and better medical services to the American people.

If American physicians must have an objective slogan, let it be *Better Medical Care for Every American Citizen*.

Nursing Practice Act

THE Todd Law relating to the practice of nursing became effective July 1, 1938, and provided a two-year waiver period after which licenses would be mandatory for registered professional nurses and for practical nurses.

Since then, Miss Emily J. Hicks, R.N., Executive Secretary of the New York State Nurses Association, reports that over 50,000 inquiries have been received in the office of the Board of Nurse Examiners. Of these, 12,500 have never followed up the first inquiry, 8,712 licenses have been issued, and 2,333 applications have been approved and the licenses are being prepared. During the last month 2,576 licenses were issued. Of the remaining 26,222 applications, much of the work necessary for completion has been done. In some cases only one record is needed before the application is presented for Board approval.

Approval of licenses has been held up principally for three reasons: (1) the lack of budgetary appropriation until May, 1939—a ten-

month period during which the work piled up because the regular staff could not be augmented, (2) the delay on the part of applicants and the schools from which they graduated in sending necessary records to complete the applications, and (3) the regulation which requires that stenographic helpers appointed from the temporary list of Civil Service workers must be changed frequently.

A number of attempts have been made to obtain licenses by fraudulent means. Only by careful study can these be detected. Other persons have applied who are mentally ill or addicted to drugs.

There is now before the legislature a bill—Assembly Introductory 878—Miss Todd—to further amend the 1938 law. The amendment provides an extension of time for one year or until July 1, 1941, the date when a license would be required for everyone who nurses the sick for hire. The Board of Nurse Examiners are reported as in favor of this change.

County News

Broome County

Dr. Stuart B. Blakely spoke on "The Psychology of Pregnancy" at the meeting of the Broome County Medical Society at the Monday Afternoon Club House, Binghamton, on January 9.

The officers for 1940 are: president, Dr. Charles M. Alaben, of Binghamton; vice-president, Dr. Elton R. Dickson, of Binghamton; secretary, Dr. Mark H. Williams, of Binghamton; assistant secretary, Dr. Henry Jackson King, of Binghamton; treasurer, Dr. Carlton H. M. Goodman, of Port Dickinson; assistant treasurer, Dr. George T. Riley, of Binghamton.

Dutchess County

Dr. Gilbert S. Tabor was elected president of the Dutchess County Medical Society at the annual meeting held at the Hudson River State Hospital on January 10. He succeeds Dr. Scott Lord Smith, who has headed the society the last two years.

Other officers elected were: Dr. James T. Harrington, vice-president; Dr. Howard P. Carpenter, secretary-treasurer; Dr. L. W. Stoller, associate secretary; Drs. A. L. Peckham, E. F. Powell, and J. J. Toomey, censors; Dr. C. Knight Deyo, delegate; Dr. Samuel E. Appel, Dover Plains, alternate delegate; and George V. L. Spratt, counselor.

An illustrated talk on "Psychiatry—the Cinderella of Medicine," was given by Dr. C. Charles Burlingame, of the Hartford Retreat, sanitarium for mental diseases.

Erie County

The Western New York Medical Plan, Inc., offering "medical insurance to low income groups," has been approved unanimously by the Erie County Medical Society. Dr. George R. Critchlow, medical director of the indemnity plan, said that "Under the plan, individual physicians give professional services at less than regular fees to beneficiaries of group insurance policies."

"We will comply with the insurance department's revised rate of schedule of maximum income for participants—\$1,800 for an individual, \$2,500 for husband and wife, and \$3,000 for a family," he said.

The plan will be operated in Erie, Genesee, Niagara, Chautauque, Cattaraugus, Wyoming, Orleans, and Allegany counties. Dr. Critchlow said 500 doctors had enrolled, adding that "a campaign to enroll the remaining 1,200 in our district will be started immediately."

The Section of Medicine of the Buffalo Academy of Medicine met on January 10 at the Buffalo Museum of Science, Humboldt Park, for a "Therapeutic Forum." The master of ceremonies was Dr. L. Maxwell Lockie, Professor of Therapeutics, and the following group discussed the questions submitted: Dr. Clayton W. Greene, professor of medicine; Dr. A. H. Aaron, clinical professor of medicine; Dr. David Miller, professor of medicine; Edward J. Meyer, Memorial Hospital; Dr. Arthur J. Reissig, Endocrinology Clinic; Outpatient Department, Buffalo

General Hospital, Mr Mearl Pritchard, president, Buffalo Academy of Pharmacy, Mr Raymond Schmitz, president, Regional Branch of American Pharmaceutical Association.

A dermatology program was presented at the meeting on January 17

Monroe County

Governors of the Monroe County Medical Society on January 15 lifted a traditional ban and, inaugurating a new educational program authorized lecturers assigned by its speakers' bureau to discuss various phases of controversial medical legislation

Effect of the action taken at a meeting of the governing board in the Academy of Medicine was to give physicians who discuss such controversial subjects as the proposed Wagner Health Act the official blessing of the society. Similar addresses by assigned speakers have been frowned upon in the past, although many requests for assignment of speakers on the subject have been received from various organizations in the society's jurisdiction

Value of organized community health efforts in maternity cases was statistically proved to physicians, nurses, and public health officials on January 10 at a meeting in the Rochester Academy of Medicine, at which it was reported that the lives of 56 mothers had been saved in Rochester during the last six years because of such measures

The report, delivered by Dr James K. Quigley, chairman of the Maternal Welfare Committee of the County Medical Society, showed a decrease from 4.1 deaths per 1,000 births in 1933 to 1.9 per 1,000 in 1939. Based on figures compiled by the committee, that means an actual life-saving accomplishment of 56 mothers, Dr Quigley said

The conference, attended by physicians, nurses, and health education workers, climaxed a seven-year study of preventable maternal deaths made by the Medical Society committee with the cooperation of hospitals, dispensaries, and other medical associations

A 50-per-cent decline in pneumonia deaths in Monroe County in the last three years is reported by the Pneumonia Advisory Committee of the County Medical Society in the annual pneumonia issue of the society's bulletin

Dr Edward G. Whipple, chairman of the committee which has been making an intensive study of new pneumonia treatments, declared that an important reason was the "effort of organized medicine to popularize knowledge on the subject both among physicians and laymen."

Credit for the curtailed mortality also was assigned to both the use of antipneumonia serums and the drug, sulfapyridine. Fears that physicians were unwise in depending entirely on the drug, which has dramatic results, were raised in the bulletin's main article by Dr George V. Taplan of the Pneumonia Control Committee.

Basing conclusions upon the committee's studies, Dr Taplan urged that physicians consider the use of both drug and serum in cases where dangerous factors complicated the disease.

In order to do this, the physician urged that pneumonia types be determined and blood cultures be made of all patients, that a majority

of patients be hospitalized to assure full benefit of new therapies, that sulfapyridine be given all patients as soon as diagnosis is made, providing that no contraindications existed, that serum be given to all cases for which they are available and which fail to respond to the drug within twenty-four to thirty-six hours, that physicians keep accurate records of all cases in order to evaluate new treatments

Jefferson County

The Medical Society of Jefferson County met on January 11, at the Black River Valley Club. An address on "Gallbladder Disease" was given by Dr Plimpton Gupitt, assistant professor of surgery, Strong Memorial Hospital, Rochester. At 5:00 P.M. a tumor conference was held at Mercy Hospital, with a study of two interesting cases

Kings County

Socialized medicine was attacked as unwarranted interference by "politicians" with the doctors by Dr Daniel A. McAteer on January 16 in his inaugural address as president of the Kings County Medical Society at the meeting in the society's headquarters, 1313 Bedford Avenue, Brooklyn.

To combat any effort by the Federal Government to interfere with the doctors, Dr McAteer suggested that \$100 be raised from each of the more than 2,000 county medical societies throughout the United States "to buy many hours of radio time, print thousands of columns of newspaper advertising."

Such publicity, he contended, would "combat the false propaganda circulating against our profession and convert to our cause millions of persons who have never heard the medical side of the present controversy."

Guest speakers included Dr Wheelan D. Sutliff, assistant director of the pneumonia-control division of the City Health Department, on "Sulfapyridine Therapy for Pneumonia," and Dr Josephine B. Neal, associate director of the bureau of laboratories of the City Health Department, on "Chemotherapy in Meningitis."

Private hospitals in New York City are attempting to "dominate" the county medical societies in order to quash proposals that might reduce their profits, Dr Pasquale J. Imperato, chairman of the scientific committee of the South Brooklyn Medical Society, charged at a meeting of the society in St. John's University, Downtown Division, on January 11.

Associate Prof. Burgess L. Gordon of the Jefferson Medical School, Philadelphia, read a paper on "Medical Views Concerning Thoracic Surgery," which was later discussed by Dr Thomas A. McGoldrick and Dr Arthur Buchanan. Dr Andrew Porrazzo, president of the society, presided.

Dr Alirio Diaz Guerra, a physician and former export manager of Sharp & Dohme, manufacturing chemists, of 78 Varick Street, died of a heart attack on January 15 at his home, 855 Ocean Avenue, Brooklyn. He was seventy-seven years old.

Dr Guerra served as Secretary of State and Minister of Public Instruction during the second administration of the late President Joaquin Crespo of Venezuela. He previously had been

ganizational resources to the government and is ready to cooperate to the limit of its ability

The American Health Program has been writing itself for one hundred and eighty-eight years since Benjamin Franklin opened the first hospital in America in 1752

The American Medical Association has been motorizing this program for the last ninety-four

years cherishing an ambition not only to conserve all of the verities and values of this medical service evolution, but the projection of them into new objectives for the delivery of better and better medical services to the American people.

If American physicians must have an objective slogan, let it be *Better Medical Care for Every American Citizen*

Nursing Practice Act

THE Todd Law relating to the practice of nursing became effective July 1, 1938, and provided a two-year waiver period after which licenses would be mandatory for registered professional nurses and for practical nurses

Since then, Miss Emily J Hicks, R N, Executive Secretary of the New York State Nurses Association, reports that over 50,000 inquiries have been received in the office of the Board of Nurse Examiners. Of these, 12,500 have never followed up the first inquiry, 8,712 licenses have been issued, and 2,333 applications have been approved and the licenses are being prepared. During the last month 2,576 licenses were issued. Of the remaining 26,222 applications, much of the work necessary for completion has been done. In some cases only one record is needed before the application is presented for Board approval

Approval of licenses has been held up principally for three reasons (1) the lack of budgetary appropriation until May, 1939—a ten-

month period during which the work piled up because the regular staff could not be augmented, (2) the delay on the part of applicants and the schools from which they graduated in sending necessary records to complete the applications, and (3) the regulation which requires that stenographic helpers appointed from the temporary list of Civil Service workers must be changed frequently

A number of attempts have been made to obtain licenses by fraudulent means. Only by careful study can these be detected. Other persons have applied who are mentally ill or addicted to drugs

There is now before the legislature a bill—Assembly Introductory 878—Miss Todd—to further amend the 1938 law. The amendment provides an extension of time for one year or until July 1, 1941, the date when a license would be required for everyone who nurses the sick for hire. The Board of Nurse Examiners are reported as in favor of this change

County News

Broome County

Dr Stuart B Blakely spoke on "The Psychology of Pregnancy" at the meeting of the Broome County Medical Society at the Monday Afternoon Club House, Binghamton, on January 9

The officers for 1940 are president, Dr Charles M Alaben, of Binghamton, vice-president, Dr Elton R. Dickson, of Binghamton, secretary, Dr Mark H Williams, of Binghamton, assistant secretary, Dr Henry Jackson King, of Binghamton, treasurer, Dr Carlton H M Goodman, of Port Dickinson, assistant treasurer, Dr George T Riley, of Binghamton

Dutchess County

Dr Gilbert S Tabor was elected president of the Dutchess County Medical Society at the annual meeting held at the Hudson River State Hospital on January 10. He succeeds Dr Scott Lord Smith, who has headed the society the last two years

Other officers elected were Dr James T Harrington, vice-president, Dr Howard P Carpenter, secretary-treasurer, Dr L W Stoller, associate secretary, Drs A L Peckham, E F Powell, and J J Toomey, censors, Dr C Knight Deyo, delegate, Dr Samuel E Appel, Dover Plains, alternate delegate, and George V L Spratt, counselor

An illustrated talk on "Psychiatry—the Cinderella of Medicine," was given by Dr C Charles Burlingame, of the Hartford Retreat, sanitarium for mental diseases

Erie County

The Western New York Medical Plan, Inc., offering "medical insurance to low income groups," has been approved unanimously by the Erie County Medical Society. Dr George R. Critchlow, medical director of the indemnity plan, said that "Under the plan, individual physicians give professional services at less than regular fees to beneficiaries of group insurance policies

"We will comply with the insurance department's revised rate of schedule of maximum income for participants—\$1,800 for an individual, \$2,500 for husband and wife, and \$3,000 for a family," he said

The plan will be operated in Erie, Genesee, Niagara, Chautauqua, Cattaraugus, Wyoming, Orleans, and Allegany counties. Dr Critchlow said 500 doctors had enrolled, adding that "a campaign to enroll the remaining 1,200 in our district will be started immediately"

The Section of Medicine of the Buffalo Academy of Medicine met on January 10 at the Buffalo Museum of Science, Humboldt Park, for a "Therapeutic Forum." The master of ceremonies was Dr L Maxwell Lockie, Professor of Therapeutics, and the following group discussed the questions submitted: Dr Clayton W Greene, professor of medicine, Dr A H Aaron, clinical professor of medicine, Dr David Miller, professor of medicine, Edward J Meyer, Memorial Hospital, Dr Arthur J Reersig, Endocrinology Clinic, Outpatient Department, Buffalo

General Hospital, Mr Mearl Pritchard, president, Buffalo Academy of Pharmacy, Mr Raymond Schnitz, president, Regional Branch of American Pharmaceutical Association

A dermatology program was presented at the meeting on January 17

Monroe County

Governors of the Monroe County Medical Society on January 15 lifted a traditional ban and, inaugurating a new educational program, authorized lecturers assigned by its speakers' bureau to discuss various phases of controversial medical legislation

Effect of the action taken at a meeting of the governing board in the Academy of Medicine was to give physicians who discuss such controversial subjects as the proposed Wagner Health Act the official blessing of the society. Similar addresses by assigned speakers have been frowned upon in the past, although many requests for assignment of speakers on the subject have been received from various organizations in the society's jurisdiction

Value of organized community health efforts in maternity cases was statistically proved to physicians, nurses, and public health officials on January 10 at a meeting in the Rochester Academy of Medicine, at which it was reported that the lives of 56 mothers had been saved in Rochester during the last six years because of such measures

The report, delivered by Dr James K. Quigley, chairman of the Maternal Welfare Committee of the County Medical Society, showed a decrease from 4.1 deaths per 1,000 births in 1933 to 1.9 per 1,000 in 1939. Based on figures compiled by the committee, that means an actual life-saving accomplishment of 56 mothers, Dr Quigley said

The conference, attended by physicians, nurses, and health education workers, climaxed a seven-year study of preventable maternal deaths made by the Medical Society committee with the cooperation of hospitals, dispensaries, and other medical associations

A 50-per-cent decline in pneumonia deaths in Monroe County in the last three years is reported by the Pneumonia Advisory Committee of the County Medical Society in the annual pneumonia issue of the society's bulletin.

Dr Edward G. Whipple, chairman of the committee which has been making an intensive study of new pneumonia treatments, declared that an important reason was the 'effort of organized medicine to popularize knowledge on the subject both among physicians and laymen.'

Credit for the curtailed mortality also was assigned to both the use of antipneumonia serums and the drug, sulfapyridine. Fears that physicians were unwise in depending entirely on the drug, which has dramatic results, were raised in the bulletin's main article by Dr George V. Taplan of the Pneumonia Control Committee.

Basing conclusions upon the committee's studies, Dr Taplan urged that physicians consider the use of both drug and serum in cases where dangerous factors complicated the disease.

In order to do this, the physician urged that pneumonia types be determined and blood cultures be made of all patients, that a majority

of patients be hospitalized to assure full benefit of new therapies, that sulfapyridine be given all patients as soon as diagnosis is made, providing that no contraindications existed, that serum be given to all cases for which they are available and which fail to respond to the drug within twenty-four to thirty-six hours, that physicians keep accurate records of all cases in order to evaluate new treatments

Jefferson County

The Medical Society of Jefferson County met on January 11, at the Black River Valley Club. An address on "Gallbladder Disease" was given by Dr Plimpton Guptill, assistant professor of surgery, Strong Memorial Hospital, Rochester. At 5 00 p.m. a tumor conference was held at Mercy Hospital, with a study of two interesting cases

Kings County

Socialized medicine was attacked as unwarranted interference by "politicians" with the doctors by Dr Daniel A. McAteer on January 16 in his inaugural address as president of the Kings County Medical Society at the meeting in the society's headquarters, 1313 Bedford Avenue, Brooklyn.

To combat any effort by the Federal Government to interfere with the doctors, Dr McAteer suggested that \$100 be raised from each of the more than 2,000 county medical societies throughout the United States "to buy many hours of radio time, print thousands of columns of newspaper advertising."

Such publicity, he contended, would 'combat the false propaganda circulating against our profession and convert to our cause millions of persons who have never heard the medical side of the present controversy.'

Guest speakers included Dr Wheelan D. Sutliff, assistant director of the pneumonia-control division of the City Health Department, on "Sulfapyridine Therapy for Pneumonia," and Dr Josephine B. Neal, associate director of the bureau of laboratories of the City Health Department, on 'Chemotherapy in Meningitis.'

Private hospitals in New York City are attempting to "dominate" the county medical societies in order to quash proposals that might reduce their profits, Dr Pasquale J. Imperato, chairman of the scientific committee of the South Brooklyn Medical Society, charged at a meeting of the society in St. John's University, Downtown Division, on January 11.

Associate Prof. Burgess L. Gordon of the Jefferson Medical School, Philadelphia, read a paper on "Medical Views Concerning Thoracic Surgery," which was later discussed by Dr Thomas A. McGoldrick and Dr Arthur Buchanan. Dr Andrew Porrazzo, president of the society, presided.

Dr Alirio Diaz Guerra, a physician and former export manager of Sharp & Dohme, manufacturing chemists, of 78 Varick Street, died of a heart attack on January 15 at his home, 855 Ocean Avenue, Brooklyn. He was seventy-seven years old.

Dr Guerra served as Secretary of State and Minister of Public Instruction during the second administration of the late President Joaquin Crespo of Venezuela. He previously had been

private secretary to General Crespo. In 1884 Dr. Guerra was editor of *El Liberal*, a periodical published in Colombia.

New York County

The Medical Society of the County of New York met on January 22 at the New York Academy of Medicine Building and listened to this program: 1. address of the retiring president, Dr. Howard Fox, 2. address of the incoming president, Dr. Walter P. Anderton, 3. address "Diagnostic Aids in the Surgery of the Brain," Dr. Wilder Penfield, chief of neurological surgery, McGill University, by invitation, 4. discussion. Dr. Tracy J. Putnam, professor of neurology and neurosurgery, Columbia University, by invitation.

The appointment of an executive secretary for a term of five years brought out considerable discussion.

The Special Committee on Infant Mortality of the Medical Society of the County of New York announces that the group meetings held each month at the New York Academy of Medicine are now open to all members of the society.

At these monthly meetings selected cases of infant deaths are presented and discussed by the members of the committee and guests. Especial attention is paid to the obstetric phase of the problem. The meeting is then addressed by some outstanding man on some subject with which he is particularly familiar.

A meeting was held at the New York Academy of Medicine on Wednesday afternoon, January 24. After discussion of cases, Dr. Samuel Frant, Epidemiologist of the City of New York and Director of the Bureau of Preventable Diseases, spoke on "Epidemic Diarrhea of the Newborn."

Dr. Walter C. Montgomery, war-time division surgeon of the Twenty-seventh Division, A. E. F., who received many decorations for his services in action, died on January 15 after an illness of two years. Dr. Montgomery, whose home was at 214 West Ninety-second Street, was sixty-one years old.

A lieutenant colonel in the New York National Guard, he had seen border service with the troops sent to Mexico, and upon the entrance of this country into the World War went to France with the Twenty-seventh Division. He was decorated by France, Belgium, and Poland.

In 1920, at ceremonies in Central Park, the Distinguished Service Medal was presented to him by Lieut. Gen. Robert Lee Bullard. His citation read:

"When confronted with a shortage of personnel he displayed marked initiative and resourcefulness in organizing additional sanitary personnel."

He conducted the evacuation of 4,000 casualties in four days of action along the Hindenburg Line.

Two new pamphlets, *Lymphogranuloma Venereum and Chancroid* and *Clinical Digest of Syphilis in Pregnancy*, are now available without cost to physicians from the Bureau of Social Hygiene, Department of Health, 125 Worth Street, New York City.

The pamphlets were prepared by the Bureau in cooperation with the New York State Department of Health and the United States Public Health Service. Some fifty leaflets on social

hygiene for the profession and the laity are available from the Bureau.

Niagara County

The Niagara Falls health authorities have obtained what are believed to be the first convictions for violations of a recently adopted amendment to the State Sanitary Code restricting the sale of raw milk and cream in cities or health districts. Within a single week, says *Health News* (Albany), two dairymen operating farms within the city limits were prosecuted for selling small quantities of raw milk on the premises. Each was fined \$25 and given a suspended sentence on a charge of violating Regulation 20, Chapter III, of the Code which provides in part:

"No milk shall be held, kept, offered for sale, transported, or delivered in any municipality or health district, for human consumption in fluid form in such municipality or health district, except milk to be pasteurized which is enroute to or stored at approved plants, unless such milk meets the requirements of this chapter and of local health regulations, if any, for a grade of milk permitted to be sold for human consumption in fluid form in such municipality or health district."

More recently a woman was apprehended and tried on a charge of transporting raw milk within the city limits. It is expected that additional cases in which evidence has already been obtained will be prosecuted without delay.

Vigorous enforcement of this state sanitary code requirement has been undertaken in an effort to avert serious epidemics of milk borne disease which may occur if the distribution of raw milk continues unrestricted. According to the *Niagara Falls Gazette* which has taken active part in the drive, the principal difficulty is the increasing number of raw milk stands, some of which are located just outside of the city limits, at which farmers sell to Niagara Falls residents who either take the milk home for their own consumption or resell it to friends and relatives. Within the past six months a serious outbreak of scarlet fever occurred in Medina and another in Hornell, both of which were traced to raw milk bootlegged from farms on the outskirts of these communities.

Oneida County

Dr. F. John Rossi is the new president of the Medical Society of Oneida County.

He was named to head the 1940 slate of officers on January 9 at the annual meeting at which Dr. Paul P. Gregory, Rome, retiring president, presided and made his final report.

Other officers chosen: vice president, Dr. J. B. Lawler, Vernon; secretary, Dr. J. I. Farrell; treasurer, Dr. H. D. McFarland; librarian, Dr. T. Wood Clark; board of censors, Dr. W. C. Schintzius, Dr. M. T. Powers, Dr. B. F. Golly, Dr. P. P. Gregory, delegate for two years to the State Medical Society, Dr. Andrew Sloan, alternate, Dr. H. N. Squier. Delegates named last year for two-year terms are Dr. William Hale, Jr., and Dr. J. F. Kelley.

The Utica Academy of Medicine held a dinner meeting with a symposium on cancer as the feature of the session on January 18.

Papers were read on cancer of the breast and on the effectiveness of surgery and radium in

treating a specific type of cancer. Speakers included Dr. Albert G. Swift, director of surgery, Dr. Donald S. Childs, director of x-ray, and Dr. J. Howard Ferguson, pathologist, all of Syracuse University, and Dr. W. B. Dickson, Utica.

Discussions were opened by Dr. Hyzer Jones, Dr. Robert C. Hall, and Dr. C. S. Gallagher.

Richmond County

Talks on medical economics were delivered at a meeting of the Richmond County Medical Society on January 10 by Dr. Frederick Coonley, Dr. E. V. Catalano, and Dr. C. Douglas Walsh.

The meeting was held in the Richmond Health Center, Stuyvesant Place, St. George. Dr. H. A. Cochrane presided.

St. Lawrence County

From his sickbed in a Utica hospital, Harold C. Stephenson, director of the Hospital Plan, Inc., telephoned a scheduled address to the St. Lawrence County Medical Society meeting in Ogdensburg, on January 11, explaining the new Medical and Surgical Care, Inc., plan.

As a member of the Hospital Plan, which he heads as executive director, he had \$4.50 of his daily hospital expenses, as well as \$1 a day for drugs, dressings, and use of the operating room, paid during the time he was a patient there.

The medical society meeting was one of several such groups he is scheduled to address to outline the new medical service insurance plan recently approved by the state. Doctors in the thirteen counties to be covered by the plan will be organized into sponsoring bodies.

His telephone talk was in the form of a question-and-answer conversation with the president of the society. The president previously had read a paper prepared by Stephenson to the fifty doctors meeting in the A. Barton Hepburn Hospital in Ogdensburg.

The doctors then asked questions which the president relayed to Stephenson over the telephone. Stephenson's answers, by a special arrangement with the telephone company, came

out of a loud speaker at the other end of the line so that they could be heard by all present at the meeting.

Schoharie County

Dr. Edgar Zeh, of Waterford, who died on January 10, had practiced medicine there for over fifty years.

Westchester County

The Westchester County Medical Society announced on January 8 that it has urged the New York State Medical Society to recommend legislation at the present session of the state legislature to forbid the sale of sulfanilamide except by prescription of a licensed physician.

"It is our belief," the society stated through Dr. Edward H. Marsh, chairman of the society's Public Health Committee, "that the ethical pharmacists recognize their moral responsibilities in relation to 'across-the-counter' sale of dangerous drugs, but they should be protected against the competition of their less ethical colleagues, some of whom have apparently not refused to dispense these drugs on demand."

In an article appearing in the current issue of the *Westchester Medical Bulletin*, the County Medical Society calls attention to the need of this legislation and points out that last year the people of the United States consumed 373,875 pounds, or about 187 tons of sulfanilamide.

James E. Bryan of White Plains, executive secretary of the Westchester Medical Society, has been elected president of the board of directors of the Westchester Tuberculosis and Health Association. He succeeds Dr. W. Godfrey Childress, head of the tuberculosis division at Grasslands Hospital.

Mr. Bryan said income from sale of Christmas seals last year was greater than in any year since 1930. He also pointed out that since the Association was organized in 1919, tuberculosis deaths in Westchester have dropped from 105 per 100,000 of population each year to 38 per 100,000 last year.

Deaths of New York State Physicians

Name	Age	Medical School	Date of Death	Residence
Arthur R. Bradbury	72	Buffalo	January 12	Grand Island
George A. Cherry	71	N. Y. Univ.	January 17	Manhattan
S. Welles Churchill	80	Bell	January 15	Manhattan
W. Levell Draper	75	Hahne, Chicago	January 26	Niagara Falls
Charles H. Grube	82	N. Y. Univ.	January 21	Manhattan

Public Health News

Editorial Note Under this title will appear from time to time information on matters pertaining to Public Health, collated by the Committee on Public Health and Education of the Council of the Medical Society of the State of New York

Antipneumococcic Serum

THE Department of Health of the State of New York, according to Dr Edward S Rogers, director of its Bureau of Pneumonia Control, is anxious to acquaint all of the physicians in the state outside of the metropolitan area with the present availability of antipneumococcic serums of the higher types. Announcements are being published in the *Health News* and through the district offices of the department.

In view of the favorable reports received from the cooperating medical centers on the effectiveness of the serums and the low incidence of reactions, types VII and VIII antipneumococcic rabbit serums were made available in September for general distribution by the Division of Laboratories and Research. Supplies are maintained by district laboratory supply stations at

Albany (Central Laboratory)	Ogdensburg
Binghamton	Olean
Buffalo	Poughkeepsie
Cooperstown	Riverhead
Corning	Rochester
Glens Falls	Syracuse
Kingston	Warsaw
Middletown	White Plains
Mincola	Yonkers

Increase in the number of stations distributing these serums will depend on the supplies available and the demands for them. Seven types of antipneumococcic serums now are being distributed, types I, IV, and V (horse) and types II, VII, VIII, and XIV (rabbit) and are available in the stations listed above. Type I serum is also distributed through ninety six other stations and type V serum through fifty five, the location of these stations is given in the list of district laboratory supply stations that was sent to physicians in the state in July, 1938. A revised edition will be issued this year. If any difficulty in obtaining serum arises, the district state health officer or the Central Laboratory should be consulted as to the nearest station where it can be obtained.

As an additional service in connection with the pneumonia control program, blood culture outfits are now being supplied through stations distributing antipneumococcic serum to physicians in districts where such facilities cannot otherwise be provided. Forty-six stations have been furnished the outfits.

MENTAL ILLNESS NOW CURABLE

"Mental illness can practically all be cured," Dr Ralph W Bohn, clinical director of the Gowanda State Hospital, told members of the Dunkirk Rotary Club in a recent address.

Describing the care of the mentally sick, Dr Bohn said that nearly any disease of this type can be cured if it is discovered in time and proper treatment is given.

"We no longer have insane asylums," the speaker said. "They are mental hospitals, and 24 per cent of patients are voluntary admissions."

About 1 person of every 20 in the state will require treatment at one time or another, he said, but few cases are hopeless if treated in time. About 70 per cent of the patients leave the first year. Of these, 40 per cent are completely cured and the rest are well along the road toward becoming well again.

"It is just as hopeless to treat far-advanced cases of mental illness as it is to treat advanced cases of tuberculosis or diphtheria or any other disease," Dr Bohn said.

Gradually the department is building up a co-

ordinated information service of educators, ministers, public health nurses, as well as physicians who note and report possible cases of mental derangement. Through these agencies the illnesses may be discovered and treated in time.

There are approximately 100,000 patients in the mental hospitals of the state, he said, maintained at a yearly cost of \$30,000,000. Patients who are able pay for their treatment, but all, prince or pauper, receive the same care.

Mental illness, despite popular ideas, has nothing to do with the nerves. It is entirely emotional and can usually be traced to a desire to "escape from it all." Trained psychiatrists often find the roots of mental illnesses dating back many years to the patient's childhood, he told the group.

"There is no more reason to be ashamed of having been mentally sick than there is to be ashamed of having been ill physically. If we can only get people to boast about their treatment at the hospital as they do about 'my operation' our work will be made much easier."

Hospital News

The Federal Hospital Program

IF REPORTS of a recent presidential interview with the press are accurate, the Administration is considering a program of federal hospital construction complying in several essential respects with the platform of the A M A , observes the *New York Medical Week*. The A M A , it will be remembered, specifies that new institutions should be erected by the federal government only where needs exist which local agencies cannot supply. It stipulates local administration and control of such institutions. According to United Press accounts, the President recognizes the wisdom of these provisions.

Both the Wagner and the Harrison bills made the mistake of insisting on matched grants: a state could receive from the federal government only such amounts as it was prepared to duplicate. This provision defeats the purpose of federal assistance by making the largest sums available to the richest states. A state too poor to provide its own hospitals is too poor to match a large federal grant. A state rich enough to qualify for extensive subsidies usually has comparatively good health facilities.

Since federal aid is designed to alleviate need, it should be granted solely on the basis of need. Every state should be required to do its utmost before receiving help from Washington. When such help is given, it should be meted out in accordance with health requirements, even if the state is unable to match federal funds.

Under the plan attributed to President Roosevelt by United Press, the federal government would build and retain title to hospitals but local authorities would maintain and operate them. The United States Public Health Service and a committee of physicians would pass on all plans and investigate the ability of localities under consideration to manage the institutions built for them.

There would be no attempt at grandiose

medical centers running into millions of dollars. The average cost would be about \$150,000 for a 100-bed hospital complete with clinic, operating room, and laboratory.

It is undisputed that the establishment of hospitals in sections now lacking them would contribute to the health of the people living in those areas. Organized medicine is eager to aid in the development of necessary health facilities. If President Roosevelt's views on federal hospital construction are correctly described above, concludes the *Medical Week*, they furnish a basis for cooperation.

The report was confirmed on January 30 when the President, in a message to Congress, asked an appropriation of \$7,500,000 to \$10,000,000 for building 50 hospitals as a modest start to improve present conditions. And on February 1 a bill was introduced jointly by Senators Wagner of New York and George of Georgia to appropriate \$10,000,000 for this purpose. The operation of the program was described by the Senators, in a statement, as follows:

"Localities desiring to participate in the benefits contemplated by the legislation must show that additional hospital facilities are needed, and must give satisfactory assurances that such hospitals will be available to the public under appropriate conditions will be maintained in good repair, and will be utilized in furnishing services according to sound professional and personnel standards, as defined in regulations to be prescribed."

"The administration of the program will be guided by a national advisory hospital council, consisting of the Surgeon-General as chairman and six members selected by him from leading medical or scientific authorities who are outstanding in matters pertaining to hospital and other public health services."

Newsy Notes

Husband as well as wife must be insured at least ten months if the wife is to receive maternity coverage under the Rochester Hospital Service Corporation insurance plan after January 1, 1941, the corporation has decided.

The change from the present rule that only the wife need be insured resulted from heavy maternity costs, according to Sherman D. Meech, managing director of the corporation.

Until March 1 of this year, corporation directors have voted, subscribers may add any eligible family members not insured at present, while a third change enables insured parents to obtain coverage for ninety-day-old infants who are in good health.

A gain of 20,677 members during 1939 was reported at the annual meeting of the Hospital Plan, Inc., of Utica, on January 15, at which time officers and directors were re-elected.

The membership is now 51,367, according to H. C. Stephenson, managing director. The insurance plan, which guarantees payment of certain hospital expenses for members who pay a specified premium, was three years old February 10.

During the past year subscribers have received care valued at \$147,552, compared to \$66,314 for 1938 and \$11,490 for 1937.

The corporation has built up an epidemic reserve of \$44,671.

Thirty-three New York hospitals, convalescent homes, and social agencies have received allocations of \$70,000 from the funds collected in the 1939 campaign of the Greater New York Chapter of the National Foundation for Infantile Paralysis, it is announced by George V. Riley, chairman of the chapter's executive committee.

MENTAL ILLNESS NOW CURABLE

"Mental illness can practically all be cured," Dr Ralph W Bohn, clinical director of the Gowanda State Hospital, told members of the Dunkirk Rotary Club in a recent address.

Describing the care of the mentally sick, Dr Bohn said that nearly any disease of this type can be cured if it is discovered in time and proper treatment is given.

"We no longer have insane asylums," the speaker said. "They are mental hospitals, and 24 per cent of patients are voluntary admissions."

About 1 person of every 20 in the state will require treatment at one time or another, he said, but few cases are hopeless if treated in time. About 70 per cent of the patients leave the first year. Of these, 40 per cent are completely cured and the rest are well along the road toward becoming well again.

"It is just as hopeless to treat far-advanced cases of mental illness as it is to treat advanced cases of tuberculosis or diphtheria or any other disease," Dr Bohn said.

Gradually the department is building up a co-

ordinated information service of educators, ministers, public health nurses, as well as physicians who note and report possible cases of mental derangement. Through these agencies the illnesses may be discovered and treated in time.

There are approximately 100,000 patients in the mental hospitals of the state, he said, maintained at a yearly cost of \$30,000,000. Patients who are able pay for their treatment, but all, prince or pauper, receive the same care.

Mental illness, despite popular ideas, has nothing to do with the nerves. It is entirely emotional and can usually be traced to a desire to "escape from it all." Trained psychiatrists often find the roots of mental illnesses dating back many years to the patient's childhood, he told the group.

"There is no more reason to be ashamed of having been mentally sick than there is to be ashamed of having been ill physically. If we can only get people to boast about their treatment at the hospital as they do about 'my operation' our work will be made much easier."

Plans for the proposed new four-story addition to Iola Sanatorium (Monroe County Tuberculosis Sanatorium) are well advanced and work will begin in the spring.

Designed to double the clinical capacity of the sanatorium and enlarge laboratory and treatment facilities, the added wing will cost between \$100,000 and \$150,000.

It is proposed to construct the addition as a WPA project.

The Greenwich Hospital Association has won the right to erect a \$1,250,000, five-story building despite the objections of a lone property-owner, who said it would "spoil the character of Greenwich."

The Board of Appeals of the Greenwich Zoning Commission granted permission to erect the building, on condition that the height does not exceed the 66 feet shown on the plans.

Plans have been filed for a \$100,000 addition to St. Agnes Hospital, a wing devoted to the care of crippled children, at White Plains.

The structure will be two stories high, in the shape of a Maltese cross, which will permit a maximum of sunlight and air. It will be constructed of brick and stone and will have a minimum capacity of forty-eight beds in addition to surgical and therapy rooms.

The wing was made possible by a donation of \$100,000 from the Martha K. Hall Foundation of New York, which has made funds available

to a number of Catholic, Protestant, and Jewish charities.

In connection with an extensive modernization and improvement program which has been carried on at Crouse-Irving Hospital, in Syracuse, during the last three years, a new education and recreation building has been provided for the School of Nursing, heretofore a part of the hospital building. The space vacated in the hospital will be used for expanding service facilities of other departments.

The new building is located at 750 Irving Avenue, next to the Crouse-Irving nurses' homes. It contains modern, large classrooms, equipped with the latest in teaching apparatus. The new building also will serve as a recreation center for the nurses.

Plans for an outpatient building for the Coney Island Hospital, Ocean Parkway and Avenue Z, Brooklyn, have been filed by the Department of Public Works with the Department of Housing and Buildings.

The plans call for construction at an estimated cost of \$630,000 of a four-story brick and stone building at 754-814 Avenue Z, adjoining the hospital. Construction of the additional building, to contain three floors of rooms and clinics and a single floor of administrative offices, will be started early next summer.

The Tioga County General Hospital at Waverly is contemplating enlargement.

MEDICINE—AND MORE

I know of no calling which offers such a wide diversity of intellectual pleasure as that of medicine, not alone in its art and science, with an ever increasing range of new developments, but in human behavior, psychology, sociology, economics, and related activities. We follow a most useful calling, an interesting occupation filled with new and striking problems and one of the best because its only aim is the benefit of man.

Medicine is the most ancient of professions, being older than Christianity and antedating the inception of civil law. It has its own system of rewards and punishments, its own disappointments and its own glories. It is a profession that has a broadening influence on the human mind and is characterized by a most splendid charity. It is an acquisition in the best tendencies and a protection against the worst tendencies.

It constructs no trusts, it finds no monopolies, it excludes no qualified practitioner, it retains for its profit no valuable discovery and it has no standing room for the quack, the scoundrel and the charlatan.

Its best work is done in the light which beats upon its throne, not in the arena of politics encouraged by the cheers of thousands, not in the seclusion of the cloister sustained by the hope of eternal joy, but in the storm- and wind-swept country, in the streets of the village, in the boulevards of the city, on the desolate field of battle where pain and pestilence, illness and misery are combated often with none but God to see it. It furnishes a curiously checkered life, a life in which storm clouds alternate with sunbeams. With the exception of the ministry it stands closer than any other calling to the secret of eternity and watches death ever busy with her shuttle as she weaves her somber threads into the woof and warp of the affairs of men.

It seeks to mitigate human suffering, to prolong human life. These have ever been its watchwords, are still and always will be, constituting its cloud of smoke by day and its pillar of fire by night. One should enter such a profession with properly exalted ideals, with a belief in its greatness, its dignity, its stability, its real importance, its essential strength. One should resolve to learn to observe, to compare, to analyze, to study, to think, to avoid formulas, to cast out sordid thoughts, to repudiate shallowness, advertising, and vain pretensions.

In short, to be a worthy disciple of Aesculapius reflecting honor and credit on the profession and deriving from it the happiness that makes life worth while, being held in grateful remembrance by those whom one has served and in respect and esteem by the conferees with and among whom one has lived and worked.—*Irrin Abell M.D.*, from *New Haven* address, January 1939.

A campaign to bring about a drastic reduction of taxes on private hospitals is being waged by the Association of Private Hospitals of Greater New York. The Association is composed of sixty-six privately owned hospitals having an aggregate value of \$25,000,000. The Association declares that unless taxes are reduced several of the largest hospitals will have to close.

Years ago, persons suffering from Buerger's disease, an ailment resulting from inflammation of the lining of the arteries, took ocean voyages to relieve the pressure on their circulatory system. The rocking motion of the boat seemed to help them.

Today, the rocking boat is brought inside the hospital in the form of an oscillating bed. They have one of these beds at Crouse-Irving Hospital in Syracuse, as told in the local press, and physicians say that patients report relief from the slow "rolling" motion of the bed.

The device, known as a "Vasoscillator," was developed in the past year. It looks like an ordinary bed save that there is a small motor attached to the under framework.

The motor works silently and with little or no vibration so that other patients nearby are not disturbed. It is connected with a system of gears, operating at three speeds, which first raise the head of the bed to an angle of 45 degrees, then lowers the head and raises the foot to the same angle.

The movement is slow and it's possible for a patient to sleep while the bed is rocking.

Technically speaking, the motion varies the pressure in the patient's extremities by varying the position of the body. The oscillating bed at Crouse-Irving is in almost constant use and each patient is allowed six hours on it at a time.

Albany General Hospital, Albany, has opened a new type "step-saving" ward, equipped with modern private and semiprivate accommodations for thirty-one persons to meet growing patient demands.

The new layout, constructed on the second floor of Pavilion A, is designed to cut nursing costs more than 25 per cent, said Everett W. Jones hospital director.

Improvements

Ground was broken, December 27, for erection of a new twelve-story building for Lebanon Hospital at Grand Concourse and Mount Eden Avenue, in the Bronx. Two more structures will be added at a final cost of \$4,000,000, marking removal of the institution from the original site, Westchester and Cauldwell avenues.

The New York State Department of Mental Hygiene has signed contracts for the purchase of 875 acres adjoining the Pilgrim State Hospital, at Brentwood, and extending into Huntington Township as the site of a new state hospital for the insane.

There is reported to be \$6,000,000 available under the state program for construction of the

Labor-saving elements in the new ward were achieved by careful planning, explained the director. Because nurses have fewer steps to take and utility rooms are strategically placed fewer workers will be needed. Yet, said Mr. Jones, the decrease in labor does not mean a decrease in patient care.

"Hospital insurance," said Mr. Jones, "has brought hospitalization within easier financial reach of a great many more people. Our studies have shown that hospital insurance subscribers are beginning to appreciably increase the demand for private and semiprivate accommodations."

An appropriation of \$22,000 was made for reconstruction and complete renovation of the ward some time ago by the hospital's board of governors. Using much of its own maintenance department labor, the hospital kept costs of the project within \$19,500. No outside architects, engineers, or consultants were employed, the entire project being worked out by the hospital's staff.

Seventy young women observed, in January, the first anniversary of a New York Junior League project, which has developed a charitable idea into a well-established, although nonpaying, profession.

The idea is to bring books and other reading matter to the bed-sides of hospital patients. The project is the league's Central Bureau for Hospital Libraries. Through the efforts of Mrs. A. Victor Cherbonnier, who directs the bureau and the volunteer workers, it has grown into a profession involving the technical knowledge of library work, the skills of bookbinding, and an understanding of the needs and the psychology of the sick.

When it was set up a year ago, the library bureau had a few books and fewer workers. Today there are more than 2,000 selected volumes and seventy trained Junior League volunteers.

The bureau is active in fourteen voluntary and municipal hospitals. Plans for 1940 include the organization of libraries in the ninety member voluntary hospitals of the United Hospital Fund of New York which helped in the expansion and development of the project.

new hospital and that work will begin as soon as possible.

There are already three state hospitals in Suffolk County, the largest being Pilgrim State Hospital, which houses more than 9,000 patients and is the largest institution of its kind in the world. The other institutions are located at Central Islip and Kings Park. New buildings are now being constructed at the Pilgrim State and Central Islip hospitals.

Construction of a new wing at Strong Memorial Hospital, in Rochester, to cost about \$400,000 and designed eventually to double the institution's present facilities for private patients will be started in the spring, University of Rochester officials announce.

Open Door to Quackery

The Peterson chiropractic bill jeopardizes the public welfare by lowering the standards of professional education and licensing unqualified practitioners to care for the sick. Laymen who understand the relationship of medical education to health should be invited to join in the fight on this pernicious measure.

Even in comparison with osteopathic education the standards set by the Peterson bill are hopelessly inadequate. At best the latter requires only a high-school diploma and twenty-four months' study in an approved chiropractic college.

This might seem to be an unattainable condition since the New York State Department of Education has never approved any school of chiropractic. The Peterson bill has a way out, however. It waives examination for chiropractors already in practice albeit illegally. Then to make the examination easier for those who can somehow qualify, it creates a separate board of chiropractic examiners.

This is a *prima facie* attempt to avoid an impartial test of chiropractic qualifications. The basic sciences are the same for all who attempt to heal the sick. There should be but one examination for all.

It is understandable that the Peterson bill should try to set up a separate examining system for chiropractors. The curriculum it prescribes is inadequate, the candidates it considers acceptable for examination are far below the standards of medical and even osteopathic applicants. The very proposal is an admission of inferiority.

Enactment of the Peterson bill would shatter the high standards of professional education and practice in this state. Just as bad money drives out good, legal recognition of any form of quackery must ultimately compromise the whole structure of medical care.

Books

Books for review should be sent to the Book Review Department at 1313 Bedford Avenue Brooklyn, N Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers.

Open Door to Quackery

The Peterson chiropractic bill jeopardizes the public welfare by lowering the standards of professional education and licensing unqualified practitioners to care for the sick. Laymen who understand the relationship of medical education to health should be invited to join in the fight on this pernicious measure

Even in comparison with osteopathic education the standards set by the Peterson bill are hopelessly inadequate. At best the latter requires only a high-school diploma and twenty-four months' study in an approved chiropractic college.

This might seem to be an unattainable condition since the New York State Department of Education has never approved any school of chiropractic. The Peterson bill has a way out, however. It waives examination for chiropractors already in practice albeit illegally. Then to make the examination easier for those who can somehow qualify, it creates a separate board of chiropractic examiners.

This is a *prima facie* attempt to avoid an impartial test of chiropractic qualifications. The basic sciences are the same for all who attempt to heal the sick. There should be but one examination for all.

It is understandable that the Peterson bill should try to set up a separate examining system for chiropractors. The curriculum it prescribes is inadequate, the candidates it considers acceptable for examination are far below the standards of medical and even osteopathic applicants. The very proposal is an admission of inferiority.

Enactment of the Peterson bill would shatter the high standards of professional education and practice in this state. Just as bad money drives out good, legal recognition of any form of quackery must ultimately compromise the whole structure of medical care.

Heretofore Albany has steadfastly refused to open the door to unqualified sectarian practitioners. If this state is to retain its leadership in medical education and practice, the legislature must reaffirm its loyalty to the principles of the Medical Practice Act by defeating the Peterson bill.

The Radiology Bill

If it were not for the decision of the Court of Appeals in the case of *Sausser v. the New York City Health Department*, it might seem supererogatory to seek legislation defining radiology as a method of medical practice. What purpose has radiology if not to diagnose and treat disease?

True, the mere act of taking a radiograph is worthless without expert interpretation of the shadows which indicate the site and nature of a lesion. Properly taken and interpreted, however, the radiograph is one of the most valuable diagnostic agents of modern medicine.

A trustworthy explanation of radiographic findings demands full knowledge of the anatomy, physiology, and pathology of the human body—in short, a complete medical education. Nevertheless, by some strange process of reasoning, the Court of Appeals has decided that neither "taking an x-ray photograph" nor "mere explanation" of the film is "diagnosis."

The absurdity of this statement must have been apparent to the Justices for further on in the decision they modified it slightly. "It may be conceded that the reading of an x-ray photograph would be a slight and necessary step in diagnosis, but it would fall far short of what we understand by these terms." Since x-ray is often the main, and sometimes the sole, diagnostic factor, it is hard to see how it can be dismissed as a "slight," nonmedical "step in diagnosis."

Moreover, the Medical Practice Act says nothing about "steps" in diagnosis. It states that anyone practices medicine who undertakes "by any means or method to diagnose, treat or prescribe for any human disease." The decision of the Court of Appeals in the *Sausser* case contravenes this provision and exposes the public to incompetent radiologic practice at the hands of lay technicians and outright quacks.

To remedy this situation the Desmond-Vincent bill explicitly describes radiology as a medical procedure and limits its practice to persons licensed under the Medical Practice Act. It does not interfere with the activities of bona fide technicians working under professional supervision. Neither does it curtail any of the existing

prerogatives of physicians and dentists with respect to the use of roentgen rays It works no hardship on any but those who seek to practice medicine without having first qualified for this difficult, responsible work

Wholly apart from the physical dangers inherent in the improper use of x-rays and faulty interpretation of radiographic films, the Desmond-Vincent bill is an important public health measure Unless radiology enjoys the same protection as other medical procedures, its progress will lag The Desmond-Vincent bill not only assures the public of competent radiologic service but encourages continued development in this important field

The Ensuing State Meeting

It is not too early for our members to reserve May 6 to May 9 when the Medical Society of the State of New York will meet again in annual session * The more members who attend and listen to the discussions of the many problems upon which there is debate and deliberation in the House of Delegates, the more widespread will be the understanding in the profession of the situations with which it is confronted It is an educational experience and will provide the answer to the captious and flippant critic who may think that all our discussions center in self-interest Were the general public to attend, they, too, would realize that most of the debate is predicated upon concern for the public welfare, and they would be better able to comprehend the position taken by organized medicine in appraising proposals as a solution for medico-economic problems

The profession at large and the public would do well to realize that, trained as we are to judge experiments and propositions for the cure of human ills with a healthy skepticism regarding sudden and miraculous panaceas, we cannot lay aside this critical attitude when confronted by social solutions which might be worse than the ills confronting us

At the forthcoming meeting the scientific exhibit will be an education in itself Here visitors can make actual personal contact with exhibitors, each of whom is usually an enthusiast on the topic which he is presenting Pertinent questions and adequate answers will pass from man to man, and the visitor goes away very often stimulated by the contact which he otherwise could not make so easily and with an added knowledge of the topic in which he is interested

The technical exhibit this year has been much curtailed, but the quality of the products that these firms are offering to the profession and the public has been enhanced

* See announcement page 372

Heretofore Albany has steadfastly refused to open the door to unqualified sectarian practitioners. If this state is to retain its leadership in medical education and practice, the legislature must reaffirm its loyalty to the principles of the Medical Practice Act by defeating the Peterson bill.

It does not interfere with the activities of bona fide technicians working under professional supervision. Neither does it curtail any of the existing

No one more than the physician realizes the need for potent hemostatics. The continued manufacture and sale of impotent agents shows a disregard by the makers for the results of scientific study. Two of the products, bovine blood derivative and hypodermic horse serum, were shown twenty years ago to possess no coagulative action¹ and yet they are still being manufactured and used. The work of Aggeler and Lucia should make commercial houses take stock and discontinue the sale of biologicals which medicine has shown to be ineffectual.

Benzedrine in Alcoholism

The treatment of alcoholism is more and more being understood as properly belonging in the realm of psychotherapy even though the practitioners of this branch of medicine are somewhat discouraged by their efforts. The chronic alcoholic addict has a fundamental personality defect which is extremely difficult to change but failure may be due to the fact that the proper psychoanalytic approach has not as yet been found. Nevertheless, it is possible to obviate some of the physiologic and psychologic aftereffects of acute inebriation quickly and effectively by the judicious use of benzedrine sulfate.

According to Reifenstein and Davidoff,² who have investigated the action of this drug in mental states characterized by depression or self-absorption, acute alcoholic psychosis and Korsakow's syndrome in alcoholics respond well to the use of amphetamine sulfate. Acute intoxication, with its attendant boisterousness, can be made to disappear rapidly by the use of this drug. A "hang-over" is soon dissipated, both in acute and chronic alcoholism. Where the patient is institutionalized, the results are even more striking.

These authors impress us with the futility of this drug as a cure for addiction to alcoholic beverages. Somewhat analogous to vitamin B deficiency therapy in the treatment of alcoholic polyneuritis, benzedrine sulfate merely improves the psychotic and physiologic aberrations which attend acute intoxication. Neither has any effect in altering a habitual tendency toward inebriation. Reifenstein and Davidoff cannot agree with Bloomberg³ who found that the use of this drug in chronic alcoholism permitted a sufficient period of sobriety for the institution of psychotherapeutics. Nevertheless, it appears that this drug has a definite place in the therapy of some phases of acute alcoholism.

² Reifenstein, E. C., Jr. and Davidoff, E. *New York State J. Med.* 40: 247 (Feb. 15) 1940.

³ Bloomberg, W. *New England J. Med.* 220: 129 (1939).

The scientific program has been the concern of committeemen during the entire year, and the section chairmen and these committeemen have endeavored to present a program of outstanding merit.

The president is arranging our annual banquet meeting in an unusual manner. It is premature to speak of details now, but all of them will be published in a subsequent issue of the JOURNAL. The Women's Medical Society of the State of New York and the Woman's Auxiliary also meet at the same time. Arrangements are in progress so that the meetings will integrate one with the other, and thus there will be assembled at the Waldorf-Astoria this spring a very complete and satisfying intellectual feast!

A record attendance is expected. We feel that we express it conservatively when we promise that those coming to the meeting will find it unusually worth while.

Potency of Coagulants

There are many commercial preparations on the market which are offered for use as hemostatic agents by virtue of their supposed ability to increase the coagulability of blood. Some are derived from brains of a variety of animal species, some from tissue fibrinogens, and some from bovine blood and from horse serum. They are available for use either topically, *per oram*, or by hypodermic injection. Finally there are the several types of snake venom. The efficacy of all of these is extolled by their manufacturers, in many instances based upon experiments conducted on laboratory animals. But since these coagulants are to be used in humans it is of little practical value whether or not a particular product will materially shorten the coagulation time of rabbit blood. It would seem that the only valid test of potency would be the estimation of its activity on human blood.

Aggeler and Lucia,¹ using human plasma, assayed biologically the coagulative potency of seventeen of these products, and their findings reveal a great discrepancy with claims made by the manufacturers of these agents. The only substances studied that were significantly active were the crude tissue emulsions of thromboplastin intended for local use and the two snake venoms (Ferrelance and Russell viper). The fibrinogen products proved relatively impotent as coagulants and the thromboplastin intended for hypodermic use was found to be inactive. Horse serums were inactive in human hemophylic plasma except in high concentrations, and then only to a slight degree. The commercial product made from bovine blood yielded no coagulative activity in any concentration.

¹ Aggeler, P. M. and Lucia, S. P. *Am. J. M. Sc.* 199: 181 (Feb.) 1940.

No one more than the physician realizes the need for potent hemostatics. The continued manufacture and sale of impotent agents shows a disregard by the makers for the results of scientific study. Two of the products, bovine blood derivative and hypodermic horse serum, were shown twenty years ago to possess no coagulative action¹ and yet they are still being manufactured and used. The work of Aggeler and Lucia should make commercial houses take stock and discontinue the sale of biologicals which medicine has shown to be ineffectual.

Benzedrine in Alcoholism

The treatment of alcoholism is more and more being understood as properly belonging in the realm of psychotherapy even though the practitioners of this branch of medicine are somewhat discouraged by their efforts. The chronic alcoholic addict has a fundamental personality defect which is extremely difficult to change but failure may be due to the fact that the proper psychoanalytic approach has not as yet been found. Nevertheless, it is possible to obviate some of the physiologic and psychologic aftereffects of acute inebriation quickly and effectively by the judicious use of benzedrine sulfate.

According to Reifenshtein and Davidoff,² who have investigated the action of this drug in mental states characterized by depression or self-absorption, acute alcoholic psychosis and Korsakow's syndrome in alcoholics respond well to the use of amphetamine sulfate. Acute intoxication, with its attendant boisterousness, can be made to disappear rapidly by the use of this drug. A "hang-over" is soon dissipated, both in acute and chronic alcoholism. Where the patient is institutionalized, the results are even more striking.

These authors impress us with the futility of this drug as a cure for addiction to alcoholic beverages. Somewhat analogous to vitamin B deficiency therapy in the treatment of alcoholic polyneuritis, benzedrine sulfate merely improves the psychotic and physiologic aberrations which attend acute intoxication. Medical Relief in New York State

On February 8, 1940, the Council of the Medical Society of the State of New York received the following report and directed that it be published. Attention of county medical society secretaries and presidents is respectfully called to the request for local reports on medical relief. These reports are to be sent to Dr. Augustus J. Hambrook, 40 State Street, Troy, the chairman of the Council Committee on Public Relations and Economics. The report follows:

"The Committee on Public Relations and Economics regrets that it has to report its appointment in the progress of its efforts to improve the status of medical relief in this state. To the last House of Delegates, the committee reported that it had recommended to the State Department of Social Welfare a new setup for the local welfare machinery. A professional advisory committee was suggested for each county, the medical members of such committees to be appointed by the county welfare officer from a list submitted by the county medical society. Other members such as dentists and druggists were to be selected by their county organizations. It was held that all decisions be vested in this committee instead of being referred to the medical social worker. It was determined that there were thirty situations which commonly arise in the administration of medical relief which could be decided locally and thereby obviate needless and unnecessary delays. Up to a few months ago this plan seemed to have the approval of the state department.

"Included in the program was a revised fee schedule based on the Workmen's Compensation Fee Schedule, but with a reduction. It was recognized that the Workmen's Compensation Fee Schedule was the lowest which would permit the doctor to do satisfactory work and still realize a profit for his services. Welfare fees, however, are paid out of current tax funds instead of from industrial profits as in the case of Workmen's Compensation. It was felt that the doctor accepting these slightly lower fees could accept this schedule as his share of the community burden in the care of the indigent. The Welfare Manual now in force, after long discussions with representatives of the State Department of Social Welfare, was revised with apparent satisfaction on both sides.

"No definite action was taken by the department after several months of waiting. Finally, the commissioner called on November 28, 1939, a meeting in Albany with a large number of local welfare officers in attendance from different parts of the state. The committee attended this meeting, and the program as previously suggested, after two years of work, was discussed in general and in detail. The Social Welfare Department later advised the committee that the local welfare officers were not in favor of adopting the proposals of the society.

"The committee deems it wise that each county welfare officer be approached by representatives of the county medical societies in the effort to secure first-hand information as to the attitude of each welfare officer on the recommendation of the Medical Society of the State of New York for reorganization and supervision of medical relief in each county with report to the state society committee as soon as possible. The general situation existing at the moment is considered by this committee to be intolerable."

The essential features of the State Society's proposition, as presented to the House of Delegates on April 24, 1939, are as follows: (1) establishment of professional advisory committees in local welfare districts, (2) revision of fee schedules now in force, (3) reduction in the amount of red tape to the minimum needed for quick and accurate management of medical relief and the payment of fees, and (4) retention without exception by the indigent of the physician or physicians of their own choice.

SULFANILAMIDE IN THE TREATMENT OF SCARLET FEVER

The Need for a Research Point of View

A. CLEMENT SILVERMAN, M.D., Syracuse, New York

(From the Department of Pediatrics, College of Medicine and City Hospital, Syracuse, and the Bureau of Communicable Diseases, Syracuse Department of Health)

SINCE the introduction of sulfanilamide, it was logically assumed that it would prove useful in scarlet fever. Likewise, it seemed reasonable to expect that the use of sulfanilamide in the treatment of scarlet fever would throw some light on its mode of action. The reported results, however, appear to be confusing and inconclusive. At first, clinicians simply recorded the exhibition of sulfanilamide in a given number of cases and the recovery of those patients. Later, efforts were made to use the drug discriminatingly in an endeavor to arrive at some conclusion as to its effectiveness and indications. It is the purpose of this paper to examine some of the results critically, bearing in mind at the same time the vast changes that have taken place in scarlet fever itself.

It has long been known that in the last seventy-five years, scarlet fever has behaved differently from the other common communicable diseases. Seventy-five years ago, the mortality from scarlet fever in this country stood approximately at 100 per 100,000 population. By 1910, it had dropped to about nine. Provisional figures for 1938 indicate a scarlet fever mortality in the United States of one. Although many changes have taken place in these years, it is not possible to account for this phenomenal decrease on the basis of reporting, incidence, age distribution, or therapy. There is abundant evidence that the number of cases has not decreased over the years, hence it must be that fewer cases die. This is corroborated further by a similar drop in the

case fatality rate. Chapin¹ has gathered evidence on this point from various parts of the world, and he has theorized that the application of isolation and quarantine measures to scarlet fever has tended to eliminate the more virulent strains. However, the fact that mild and severe cases may occur in the same family outbreak rather tends to emphasize that changes or differences in the host may be a significant factor. I have noted that adults with fatal scarlet fever almost invariably showed also positive Schick tests, suggesting inability generally to produce antibodies.

In Syracuse, outbreaks of scarlet fever occurred in 1924 and in 1937. In both years, the number of cases reported was practically identical, 1,216 and 1,218, respectively. Sixteen deaths were recorded in 1924 and only 4 in 1937. Unfortunately, there are no further data on the 1924 outbreak comparable with those of the last outbreak.

A change in the character of a disease, such as the decrease in the severity of scarlet fever, is certain to influence our interpretation of the results of specific therapy. This was clearly apparent in 1924 when scarlet fever serum was introduced. The confusion in the reported results was striking and was brought about not only by differences in the titer and valency of the different serums employed but also by the failure to take into consideration the types of cases. Certain workers advocated the use of serum in every early case, regardless of its mildness. The occurrence of serum sickness soon discouraged its routine use. Then questions began to arise whether

*Read at the Annual Meeting of the Medical Society of the State of New York,
Syracuse, April 27, 1939*

the serum did more than neutralize the toxin and whether it had any effect in lessening septic complications. After considerable analysis, it became evident that serum was highly useful in cases showing toxemia. In such cases, an adequate dose of potent serum employed early in the disease exerts a neutralizing effect upon the toxemia, overcomes the prostration or delirium, and causes the rash to disappear in twenty-four to thirty-six hours. The dread of the fulminating toxemic cases which often showed a livid eruption, profound prostration, and an early fatal termination has practically disappeared, since such cases are now rarely encountered, but it is reasonable to expect that serum therapy in such cases would have saved many lives.

More recently, we have come to be increasingly concerned with the septic or invasive phase of scarlet fever. Severe cases may be predominantly toxemic or septic, or various combinations of these. Some cases with considerable toxicity may show but little tendency to invasiveness. There appears to be no direct relationship between toxin production and the invading properties of the streptococcus. Septic cases, too, vary a great deal in the amount of accompanying toxemia. Moreover, cases mild at the onset may, nevertheless, exhibit septic complications in the second or third week. But, on the other hand, the moderate and severe cases are much more liable to septic or invasive complications. Too, these complications are quite frequently associated conditions, really arising at the beginning of the disease—a purulent nasal discharge, enlarged and tender lymph nodes, and catarrhal or suppurative otitis media may be present at the onset and even precede the scarlatinal rash. In certain cases, the septic invasion may later extend to the mastoid cells, the meninges, or the blood stream. Certain other complications, known as sequelae, such as glomerulonephritis, adenopathy, and joint symptoms, may ensue at the end of the disease, these have been looked upon as phenomena of sensitization or allergy, and are not to be included among the

septic complications. Without a consideration of the foregoing factors, it is not feasible to make a critical evaluation of a specific mode of treatment in scarlet fever.

In beginning our observations on the use of sulfanilamide* in the treatment of scarlet fever early in 1937, we first looked for possible effects on the eruption and on the toxic manifestations. It soon became clear that sulfanilamide exerts no such influence. Chart 1 shows an example of its failure to influence the rash or the toxemia in a moderate case with a bright rash. This is in conformity with the findings of other observers and appears to show that sulfanilamide has no effect on the toxin production in scarlet fever. It was this clinical observation that made us question Osgood's conclusion from his laboratory experiments that sulfanilamide acts upon the toxin of the streptococcus.²

We next turned to the effect on septic complications. It appeared necessary, first, to form a more definite concept of septic complications, to define, if possible, the degree of invasion that constitutes complication. How much enlargement of the cervical lymph nodes can be designated as adenitis? How much injection of the drum shall be labeled catarrhal otitis media? At what point can it be said clinically that sinusitis has supervened? Moreover, most of these conditions are frequently essential phenomena in patients who are more than mildly ill—associated conditions present by the time the patient is admitted to the hospital, and absent usually in mild cases. In recent years, nearly 60 per cent of moderately ill cases hospitalized within three days from their onset showed evidence of septic conditions on admission. Since mild cases predominate nowadays, it seemed advisable to administer the drug to the moderately severe and severe cases of the septic variety. It seemed wise, therefore, to focus our attention primarily on suppurative otitis media. This is definitely objective the

* The sulfanilamide employed in the early months of 1937 was restricted to prontosil (also prontosil).

TABLE 1.—SELECTED CASES OF SCARLET FEVER TREATED AT THE CITY HOSPITAL, SYRACUSE, IN WINTER OF 1937

	Type of Specific Treatment		
	Serum	None	Sulfanilamide

Average admission temperature	102.7 F	101.8 F	102.1 F
Average duration of fever (hours)	204	112	57
Average stay in hospital (days)	27.5	29	27

ear discharges or does not discharge, it is not likely to be overlooked and it does not need to be graded

Sulfanilamide was not available for our use until the end of January, and, desiring to put as many suitable cases as possible under treatment during the next few months, we chose clinically similar cases of the same age from January as controls. Approximately 1 grain of sulfanilamide per pound was given during the febrile stage and half the dose during two or three days after the temperature became normal. The treated cases were, for the most part, denied throat irrigations or nose drops. Toxic cases treated with serum are tabulated for comparison. From Table 1, it is seen that in 19 cases that served as controls, 7 instances of suppurative otitis media were encountered, whereas in 23 similar cases treated with sulfanilamide only 2 suppurative ear cases were noted.

This series is small, however, for so variable a disease as scarlet fever. Secondly, the observations were made during an outbreak and it became apparent that the severest cases occurred early in the outbreak. By the end of March, 655 of the 1,218 cases of 1937 had been reported, and subsequently the mild cases predominated even more.

With Wesselhoft and Smith,³ I feel that a large series is necessary before one can eliminate the factor of chance variation that is so inherent in scarlet fever. In their series of 100 cases each, they had 15 cases with suppurative ears in the control group and only 6 in the sulfanilamide group. Although they speak of using selected cases, they do not give the

TABLE 2.—SELECTED CASES OF SCARLET FEVER TREATED AT THE SYRACUSE CITY HOSPITAL IN 1938 BY AGE AND SEASON

basis of type selection, except that there were no complications on admission, and they do not elaborate further.

As an indication of the care to be exercised in evaluating results, reference must be made to the series by Peters and Havard⁴ in England, who treated 150 cases with sulfanilamide and used a similar number for controls, but gave serum to 56 cases of the latter. They noted that 35 per cent developed one or more complications in the sulfanilamide group as against 56 per cent in the controls. When one examines their table of complications, however, it is seen that albuminuria, rheumatism, endocarditis, and nephritis are grouped together with the more definite septic complications, when it comes to otitis media it is found that there were 11 in their treated group and 10 in the controls, hence, the validity of their conclusions may well be questioned.

It was planned to continue more detailed observations during 1938, but following an epidemic year the incidence was low and but 128 scarlet fever patients were hospitalized. For this analysis, only those cases were selected that at the time of admission had been ill not more than three days from the onset. Although it was deemed from our previous experience that mild cases usually got along well enough without specific treatment, it was desired to include all types of cases in the group treated with sulfanilamide as well as in the group treated without this specific drug. Eighty-four cases were found suitable for study, and of these 43 had received sulfanilamide and

TABLE 3—SELECTED CASES OF SCARLET FEVER TREATED AT THE SYRACUSE CITY HOSPITAL IN 1933, BY DURATION OF FEVER

Duration of Fever	Without Sulfanilamide	With Sulfanilamide
None	6	1
1-2 days	23	15
3-4 days	7	15
5 days and over	5	12
	41	43

41 had not. In Table 2, these selected cases are grouped as to age and season and it can be seen that the distribution for age is practically identical

In Table 3 the two groups are arranged by the duration of fever. This duration refers to the time from admission to the first sustained normal temperature and does not take into account fever of a later time

Under types of disease, the cases are grouped in Table 4 as they appeared in their first examination and as they were reclassified subsequently in the light of the course during their stay in the hospital. A mild case was defined as one coming in with a temperature under 102 F and without evidences of invasion of underlying or adjacent tissues. Cases with fever of 102 F but under 105 F, and all cases with definite evidences of invasive complications when admitted were termed moderate cases. Cases with an admission fever of 105 F or over, or with fever over 102 F and having serious complications, like surgical mastoid or bacteremia, were classified as severe.

It will be noted that the changes in classification were not numerous. In the group without sulfanilamide 6 were considered moderate on admission, but subsequently 8 were graded as moderate and 1 as severe, in the sulfanilamide group, 19 were considered moderate on admission and 22 subsequently. The cases treated without sulfanilamide do not constitute a control group as a whole, since the mild cases constituted 78 per cent in this group as against 46 per cent in the sulfanilamide group.

The incidence of complications and their variety hold the chief interest. For facility in analysis, only one complication was recorded for each patient

TABLE 4—SELECTED CASES OF SCARLET FEVER TREATED AT THE SYRACUSE CITY HOSPITAL IN 1933, BY TYPE OF DISEASE AND SEPTIC COMPLICATION

Type of Disease	Without Sulfanilamide		With Sulfanilamide	
	On admission	Subsequently	On admission	Subsequently

Peritonsillitis		3	1	1
Cervical adenitis		2	4	3
Purulent rhinitis	1	—	—	5
	3	8	14	20

showing evidence of septic involvement, but the complication chosen was the most significant one or the primary one, thus, with peritonsillar abscess, cervical adenitis is quite to be expected, with suppurative otitis media, there is likely to be rhinitis or sinusitis, with mastoiditis, there is a preceding otitis media, sinusitis was not recorded unless there was unmistakable clinical evidence and was therefore included with rhinitis in this series, rhinitis refers to fairly profuse mucopurulent nasal discharge anteriorly and posteriorly. This arrangement, I think, is in consonance with clinical observations and avoids the confusion of dealing with too many multiple groupings.

Complications were also separated into those present on admission and those showing up subsequently, after a lapse of twenty-four hours or longer. From Table 4 it can be seen that the change in complications is greater, on the whole, than the change in classification of type. In the group without sulfanilamide, 3 patients with septic complications were observed on admission and the number was subsequently increased to 8. In the sulfanilamide group, 14 had septic complications on admission and this was increased to 20 subsequently. It will be noted that the proportion of patients with septic complications corresponds very closely to the proportion of moderate

CHART 1 Showing the duration of rash and toxemia not shortened by sulfanilamide

and severe cases in the two groups. When, however, attention is focused on the suppurative ear cases it is seen that in the untreated group they number 3, or 33 per cent, among the 9 patients more than mildly ill. In the sulfanilamide group there were 4 suppurative ear cases out of 23, or 17 per cent. It could be pointed out, too, that among the suppurative ear cases in the first group there was 1 surgical mastoid but none in the sulfanilamide group, and that the suppurative ear cases were increased by only 2 after admission, although 5 catarrhal ear cases were found on admission. Nevertheless, the small number of cases involved does not warrant definite conclusions.

Undue enthusiasm over individual cases has to be guarded against. It would be very easy, for example, to single out two brothers, five and seven respectively, in a family outbreak of 5 cases. Upon admission both looked like mild cases with but slight rhinitis. Both subsequently developed suppurative otitis media, bilateral in the five-year-old, right-sided in the elder brother. Sulfanilamide was given to the younger brother and he recovered, the other, without sulfanilamide, had the only mastoidectomy in this series. Nonetheless, it is one of the most unsound tendencies in practice to draw conclusions from a single case of an inherently varying morbid process. Clinical impressions have their usefulness, and in clinical studies controls are only such in part, in view of varied and subtle in-

CHART 2 Rash and toxemia not affected by large doses of sulfanilamide in first three days of illness. Prompt subsidence of fever, rash, and toxemia following serum administration.

dividual differences which cannot be wholly equated, but conclusions can be valid only if based upon clinical experience and judgment within an acceptable statistical framework.

Perhaps it may be permissible to digress for a moment to enlarge on relapse, a rare complication not listed in the table, which occurred in the untreated group. A boy of nine was admitted with a mild but typical scarlet and showed a negative Dick test and a negative rash extinction (blanching) test within twenty-four hours. On his twenty-first day he complained of sore throat, became feverish, and a rash appeared the next day which was rather scarlatinal in type. The blanching test was again negative. His throat culture and 5 cc of his serum were sent to the State Laboratory. The report stated that his culture produced toxin which in intracutaneous tests on rabbits was neutralized by antitoxin of the standard strain, No 165 (Dochez, N Y 5), but a 1:5 dilution of his serum failed to neutralize either the homologous toxin or the toxin of strain No 165.

The ease with which sulfanilamide may be given has tended to deny serum to cases that might have benefited from its use. Chart 2 shows a severe case to whom large doses of sulfanilamide were given from the onset without influencing the high fever or the toxemia and prostration, following the administration of convalescent serum, the fever dropped

CHART 3 Severe case of scarlet fever with toxemia and streptococcus bacteremia treated with sulfanilamide, serum, and transfusion

promptly, the rash began to fade, and the change in the patient was most striking. Cases of this sort appear to support the increasing evidence, both clinical and experimental, that specific antibody adds to the effectiveness of sulfanilamide.

Another illustrative case is that shown in Chart 3. This patient was admitted on the eighth day of the disease with fever of 102.6 F that did not at all measure the extreme illness of the patient. She was delirious, dehydrated, and showed a livid erythema. She had received 4 Gm sulfanilamide four days previously and 2 Gm each day for three days previous to admission. A large dose of scarlet fever serum was given intravenously and within twelve hours there was a marked change in her condition, when the temperature rose to 104.4 F, the third day of admission and the tenth day of the disease, and the blood culture taken that day revealed streptococcus bacteremia, sulfanilamide was again started and the concentration reached 5.5 mg. Her temperature became normal on the fifteenth day and she made an uneventful recovery. Two earlier (1935) cases of scarlet fever with positive blood cultures, before sulfanilamide was available, and treated with serum and transfusions ran septic temperatures for nine and five weeks, respectively. None of these gave evidence of pyemia.

The chief objection to the use of heterologous serum in scarlet fever is the occurrence of serum reactions. Chart 4 illustrates the temperature curve in a

CHART 4 Moderately severe case of scarlet fever with toxemia and septic invasion, treated with antistreptococcus serum and sulfanilamide, showing serum reaction.

moderately severe case that combined toxic and septic features. He showed toxemia, prostration, and a profuse bright red rash, there was grayish membrane on the tonsils, the cervical glands were enlarged and tender, and the profuse mucopurulent nasal discharge excoriated the upper lip. He needed serum and sulfanilamide, it was felt. Although the rash faded in a day and the fever fell to normal within sixteen hours after serum injection, it rose again within a few hours to a moderate degree, but continued from the eighth to the thirteenth day, because of serum sickness, to practically the same height as at the beginning of the sickness.

In contrast, Chart 5 presents the fever chart of a patient with a moderately severe toxic case with a deep red rash treated with sulfanilamide alone. His fever persisted for nineteen days and the rash did not fade completely till the end of the second week. He was prostrated and ill throughout that period, had troublesome emeses for four days during which time sulfanilamide was discontinued, he appeared cyanotic during the greater part of the first two weeks, complained of general pains, headache, and fatigue, and refused all food. He gave a most distinctly positive rash extinction (blanching) test which persisted for nearly two weeks. When I saw him with his physician during the second week I could not help feeling that his illness might have been shortened by serum.

CHART 5 Moderately severe toxic case of scarlet fever treated with sulfanilamide and without serum, showing the prolongation of fever and persistence of rash

administration, but by the tenth day it seemed unwise to give serum.

Physicians who tend to be wary of employing serum therapeutically often fail to be concerned over the possible taking of unwarranted risks with sulfanilamide. The literature has called attention amply to the various dangers and contraindications of sulfanilamide. Our own experience with some 500 cases has proceeded without cause for anxiety, but the vast majority have been treated at the hospital where careful observation and blood studies were available. Apart from cyanosis, drug rash, drug fever, vomiting, aching, and apathy, no serious difficulties were met. A case with febrile reaction is shown in Chart 6. This case was extremely mild and required no treatment. The physician on the case wanted to "play safe" by giving sulfanilamide. On the eighth day her temperature, which had not gone above 99.2 F previously, rose to 101.4 F and the next day to 102.4 F. She had had no symptoms before, but now became irritable and complained for three or four days of headache, general pains, anorexia, insomnia, chilliness, and depression. When one considers that in recent years about 75 per cent of our hospitalized cases have been mild, it seems unwarranted to employ in such cases any therapy that carries more risk relatively than the disease itself. The old medical aphorism, *Primum non nocere*, must not be forgotten. We should avoid doing harm

CHART 6 Mild case of scarlet fever given sulfanilamide during the first week, showing drug fever

with unnecessary treatment, however well intentioned

Summary

Attention is called first to the striking and steady change in the character of scarlet fever over the last seventy-five years, the mortality in 1938 being but one-hundredth of that in 1861. This milder form of scarlet fever caused some difficulty in the beginning in evaluating scarlet fever serum and is causing similar difficulty with sulfanilamide.

There is concurrence in the conclusion that sulfanilamide exerts no evident influence on the toxic phase of scarlet fever. There are several studies, consistent with that here reported, suggesting that sulfanilamide may lessen the incidence of suppurative ear complications, but on careful consideration of the marked variability of scarlet fever, it is felt that no series is as yet large enough to be accepted as conclusive.

A nonepidemic series of last year at the Syracuse City Hospital is analyzed on the basis of criteria formulated for designating types of severity and for differentiating complications associated with the onset of the disease from those developing subsequently, so as to provide a basis for statistical consideration. The series of 84 cases appears also to show a smaller ratio of suppurative ear conditions in the sulfanilamide group, nevertheless, it is emphasized that definite conclusions are unwarranted on the basis of a small series.

It is pointed out that sulfanilamide does not displace antistreptococcus serum for toxemic cases, and in severe cases par-taking of both the toxic and septic phases combined treatment is indicated, the literature supporting this with experimental evidence. For the sick patient, it is justifiable, under proper safeguards, to incur the risk of serum reaction or drug intolerance. It is unjustifiable, however, to apply routine treatment without thoughtful consideration of the individual case. In very mild cases to apply therapy that may cause harm goes counter to the old medical dictum *Primum non nocere*.

. . .

I am indebted to my associates on the pediatric, medical, and E N T services of the Syracuse City Hospital for assistance in the clinical study of the cases and for the privilege of including data on their private cases seen in consultation. I wish also to express appreciation for helpful cooperation from the city and state laboratories. No little credit is due to the interns.

NOTE Only these specific references are listed. No attempt has been made to cite the extensive bibliography of sulfanilamide because of its recency and ready availability. For general references on the various aspects of scarlet fever I drew on my chapter on Scarlet Fever in the volume on Pediatrics (Vol VII publ 1935), pp 843-893, Practitioners Library Appleton Century Co New York.

Discussion

Dr William J Orr, *Buffalo, New York*—I feel at this time and in this locality it is practically impossible to evaluate definitely the effectiveness of sulfanilamide in the treatment of scarlet fever. Dr Silverman's excellent critical review of the subject clearly points out many of the obstacles that are encountered.

During the past decade the clinical manifestations of scarlet fever have been so mild that practically all studies, not only in the treatment but also in the prevention of the disease, have been somewhat inconclusive.

The results obtained from the use of antistreptococcus serum in the treatment and the Dick toxin in the prevention of the disease are still being debated. Therefore, we should not feel too discouraged if the effectiveness of sulfanilamide as a therapeutic agent is still in doubt. The first mentioned procedures have been in use for over ten years, while the latter for only two or three years.

Scarlet fever and its clinical manifestations have been so mild that it has been impossible to report a controlled series of cases treated with sulfanilamide, so as to be able to include a sufficiently large group of moderately severe and severe cases to determine definitely the effect of the drug on the disease.

As the result of what has been published to date most of us share the impression that sulfanilamide is not as effective in the treatment of scarlet fever as it is in other types of infection due to streptococcus, erysipelas for example.

Until a larger amount of data are accumulated so that the toxic or severe types of the disease are in sufficient numbers to be of statistical significance, sulfanilamide should not be considered as totally inefficient.

At the present time, the best course to pursue in the management of the treatment of moderately severe or severe cases of scarlet fever should be the judicious use of serum and sulfanilamide.

Dr George R. Murphy, *Elmira, New York*—Dr Silverman's paper is timely and merits consideration. He shows clearly a sense of balance and a desire to keep his feet on the ground. He lauds the worth of sulfanilamide but warns against its dangers especially when used with overenthusiasm. He also has shown that one must be prepared to detoxify with serum, and to use serum and sulfanilamide as adjuncts to each other. In still other cases, perhaps one should consider these two agents as synergists in the treatment of a specific case—for he has brought out the need for individualization of therapy.

He has quoted Wesselhoef and Smith who are in agreement with most of his conclusions. They also feel that sulfanilamide may be of value in the prophylactic treatment of nonimmune scarlet fever contacts.

The paper of Sako, Dwan, and Platou [*JAMA* 111 995 (Sept 10) 1938] also stresses the same point of view in this question of therapy. They, too, feel the need for antitoxic substance plus sulfanilamide in certain cases.

Arthur W Chapman in the *Archives of Pediatrics* 55 560 (Sept. 28) 1938 used sulfanilamide successfully in the treatment of bacteremia of

postscarlatinal nephritis. We ourselves have recently had such a case which responded successfully to sulfanilamide and neo-prontosil.

In their recent book on scarlet fever, the Dicks state "In our experience sulfanilamide has not been of value in the toxic stage of scarlet fever but seems to be of benefit in the sinusitis, otitis media, mastoiditis, and cervical adenitis after the toxic stage has passed." From this one can see that the Dicks are in accord with Dr. Silverman, but fail to mention the use of sulfanilamide in the cases of early suppurative processes which may be present during the toxic stage.

Our clinical impression has been that sulfanilamide has definitely reduced the incidence of

suppurative types of complications arising in the course of this disease. We are well aware as Dr. Silverman states that the disease is so variable that one cannot be too dogmatic in his conclusions about therapy, and also that one must have a large number of carefully controlled cases before arriving at very definite conclusions. However, as long as scarlet fever is a disease of the streptococcus family it seems to us not only justifiable but logical that this valuable drug should be used, but with intelligent reservations.

I feel that Dr. Silverman's paper has covered the ground adequately, and that in the light of present conditions his conclusions are sound.

THE 'SALES LADY' IN THE OUTER OFFICE

The physician is quite likely to be blissfully ignorant of the importance of a courteous pleasant saleslady in the outer office, unconscious of the fact that the psychologic reaction of his patients to the office environment may contribute to a favorable or an unfavorable attitude toward himself, remarks Stanley R. Mauck in the *Ohio State Medical Journal*. Mr. Mauck is executive secretary of the Columbus Academy of Medicine and Director of the Columbus Bureau of Medical Economics. Previously he operated a private professional management service for physicians. He goes on to say that a calm, intelligent, tactful secretary, or office assistant, has set the stage in many instances for a successful career. The wrong kind of personnel may contribute to the opposite result. The art of healing, after all, contains many elements of salesmanship, and upon the physician's assistant rests part of the responsibility for the successful consummation of the patient-physician relationship.

Among the secretary's duties we would like to emphasize the importance of telephone calls. Many patients have been repelled or drawn to the physician's office as a result of the initial telephone conversation. A pleasing telephone personality is a great asset in any physician's office. Complete information about the party calling the nature of the inquiry and its importance with reference to immediate action by the physician can be easily elicited if the calls are diplomatically handled. When the physician is out, the secretary can calm the impatience and disappointment of the patient by tactful advice as to when the physician will be available or under

what circumstances he might be reached. A helpful, cooperative attitude may result in a definite appointment at a convenient later time and give the patient a satisfactory reaction, even though his immediate expectations for seeing the physician could not be gratified. There is nothing more irritating to an ill and suffering patient who calls with reference to prospective relief at the hands of the physician than to be told by a brusque voice at the other end of the telephone simply that "Dr. Blank is not in" or "The doctor does not have office hours today." There are more tactful ways of conveying negative information.

The proper handling of patients with reference to appointments requires finesse and tact. There is nothing more disconcerting to the ego of the average patient than to find that no regard is given to his previous arrangements for a specific time at which he can see the physician. It is essential that patients who arrive under previous appointments are not left waiting in the reception room to take their turn in relation to the other patients who have arrived at an earlier time, but without appointments. In handling these appointments it is necessary, however, to exercise precautions that other waiting patients are not offended or given the impression of favoritism when the late arrivals are ushered into the physician's private office ahead of the others. This situation can be diplomatically handled by an announcement to the effect "Mr. Jones, your appointment was at two o'clock and the doctor is ready to see you now," or other similar enlightening statements.

TO AID SOCIAL SECURITY BENEFICIARIES

The New York City Department of Health requests that physicians who prepare death certificates of persons insured under the Social Security Act enter the account number of every such person in the space provided. Even if the death certificate form does not call for this in-

formation, its entry immediately following the name of the deceased person will render a real service to his dependents, in order that payments to beneficiaries of workers insured under the provisions of this act may be inaugurated promptly.

It is pointed out that sulfanilamide does not displace antistreptococcus serum for toxemic cases, and in severe cases partaking of both the toxic and septic phases combined treatment is indicated, the literature supporting this with experimental evidence. For the sick patient, it is justifiable, under proper safeguards, to incur the risk of serum reaction or drug intolerance. It is unjustifiable, however, to apply routine treatment without thoughtful consideration of the individual case. In very mild cases to apply therapy that may cause harm goes counter to the old medical dictum *Primum non nocere*.

I am indebted to my associates on the pediatric, medical, and E N T services of the Syracuse City Hospital for assistance in the clinical study of the cases and for the privilege of including data on their private cases seen in consultation. I wish also to express appreciation for helpful cooperation from the city and state laboratories. No little credit is due to the interns.

Discussion

Dr William J Orr, *Buffalo, New York*—I feel at this time and in this locality it is practically impossible to evaluate definitely the effectiveness of sulfanilamide in the treatment of scarlet fever. Dr Silverman's excellent critical review of the subject clearly points out many of the obstacles that are encountered.

During the past decade the clinical manifestations of scarlet fever have been so mild that practically all studies, not only in the treatment but also in the prevention of the disease, have been somewhat inconclusive.

The results obtained from the use of anti streptococcus serum in the treatment and the Dick toxin in the prevention of the disease are still being debated. Therefore, we should not feel too discouraged if the effectiveness of sulfanilamide as a therapeutic agent is still in doubt. The first mentioned procedures have been in use for over ten years, while the latter for only two or three years.

Scarlet fever and its clinical manifestations have been so mild that it has been impossible to report a controlled series of cases treated with sulfanilamide, so as to be able to include a sufficiently large group of moderately severe and severe cases to determine definitely the effect of the drug on the disease.

As the result of what has been published to date most of us share the impression that sulfanilamide is not as effective in the treatment of scarlet fever as it is in other types of infection due to streptococcus, erysipelas for example.

Until a larger amount of data are accumulated so that the toxic or severe types of the disease are in sufficient numbers to be of statistical significance, sulfanilamide should not be considered as totally inefficient.

At the present time, the best course to pursue in the management of the treatment of moderately severe or severe cases of scarlet fever should be the judicious use of serum and sulfanilamide.

Dr George R. Murphy, *Elmira, New York*—Dr Silverman's paper is timely and merits consideration. He shows clearly a sense of balance and a desire to keep his feet on the ground. He lauds the worth of sulfanilamide but warns against its dangers especially when used with overenthusiasm. He also has shown that one must be prepared to detoxify with serum, and to use serum and sulfanilamide as adjuncts to each other. In still other cases, perhaps one should consider these two agents as synergists in the treatment of a specific case—for he has brought out the need for individualization of therapy.

He has quoted Wesselhoft and Smith who are in agreement with most of his conclusions. They also feel that sulfanilamide may be of value in the prophylactic treatment of nonimmune scarlet fever contacts.

The paper of Sako, Dwan, and Platou [J.A.M.A. 111 995 (Sept. 10) 1938] also stresses the same point of view in this question of therapy. They, too, feel the need for antitoxic substance plus sulfanilamide in certain cases.

Arthur W Chapman in the *Archives of Pediatrics* 55 560 (Sept. 28) 1938 used sulfanilamide successfully in the treatment of bacteremia of

postscarlatinal nephritis. We ourselves have recently had such a case which responded successfully to sulfanilamide and neo-prontosil.

In their recent book on scarlet fever, the Dicks state "In our experience sulfanilamide has not been of value in the toxic stage of scarlet fever but seems to be of benefit in the sinusitis, otitis media, mastoiditis, and cervical adenitis after the toxic stage has passed." From this one can see that the Dicks are in accord with Dr. Silverman, but fail to mention the use of sulfanilamide in the cases of early suppurative processes which may be present during the toxic stage.

Our clinical impression has been that sulfanilamide has definitely reduced the incidence of

suppurative types of complications arising in the course of this disease. We are well aware as Dr. Silverman states that the disease is so variable that one cannot be too dogmatic in his conclusions about therapy, and also that one must have a large number of carefully controlled cases before arriving at very definite conclusions. However, as long as scarlet fever is a disease of the streptococcus family it seems to us not only justifiable but logical that this valuable drug should be used but with intelligent reservations.

I feel that Dr. Silverman's paper has covered the ground adequately and that in the light of present conditions his conclusions are sound.

THE SALESLADY" IN THE OUTER OFFICE

The physician is quite likely to be blissfully ignorant of the importance of a courteous, pleasant "saleslady" in the outer office, unconscious of the fact that the psychologic reaction of his patients to the office environment may contribute to a favorable or an unfavorable attitude toward himself, remarks Stanley R. Mauck in the *Ohio State Medical Journal*. Mr. Mauck is executive secretary of the Columbus Academy of Medicine and Director of the Columbus Bureau of Medical Economics. Previously he operated a private professional management service for physicians. He goes on to say that a calm, intelligent, tactful secretary, or office assistant, has set the stage in many instances for a successful career, the wrong kind of personnel may contribute to the opposite result. The art of healing, after all, contains many elements of salesmanship, and upon the physician's assistant rests part of the responsibility for the successful consummation of the patient-physician relationship.

Among the secretary's duties, we would like to emphasize the importance of telephone calls. Many patients have been repelled or drawn to the physician's office as a result of the initial telephone conversation. A pleasing telephone personality is a great asset in any physician's office. Complete information about the party calling the nature of the inquiry and its importance with reference to immediate action by the physician can be easily elicited if the calls are diplomatically handled. When the physician is out, the secretary can calm the impatience and disappointment of the patient by tactful advice as to when the physician will be available or under

what circumstances he might be reached. A helpful, cooperative attitude may result in a definite appointment at a convenient later time and give the patient a satisfactory reaction, even though his immediate expectations for seeing the physician could not be gratified. There is nothing more irritating to an ill and suffering patient who calls with reference to prospective relief at the hands of the physician than to be told by a brusque voice at the other end of the telephone simply that "Dr. Blank is not in" or "The doctor does not have office hours today." There are more tactful ways of conveying negative information.

The proper handling of patients with reference to appointments requires finesse and tact. There is nothing more disconcerting to the ego of the average patient than to find that no regard is given to his previous arrangements for a specific time at which he can see the physician. It is essential that patients who arrive under previous appointments are not left waiting in the reception room to take their turn in relation to the other patients who have arrived at an earlier time, but without appointments. In handling these appointments it is necessary, however, to exercise precautions that other waiting patients are not offended or given the impression of favoritism when the late arrivals are ushered into the physician's private office ahead of the others. This situation can be diplomatically handled by an announcement to the effect "Mr. Jones, your appointment was at two o'clock and the doctor is ready to see you now," or other similar enlightening statements.

TUBERCULOSIS IN STUDENT NURSES

LEOPOLD BRAHDY, M D , New York City

WHETHER a disease belongs in the category of an occupational hazard is determined by a comparison of (a) its incidence among those engaged in one particular occupation with (b) its incidence among similar groups in other occupations. Such a comparison is difficult when the disease under consideration is common among all groups of people and exhibits wide variation according to age, sex, and many other factors. Herein I shall first present a basis for determining whether contact with tuberculous patients is a threat to the health and life of student nurses and then examine the available data.

In years past, when the physician had to rely on a stethoscope and his own acumen in diagnosing tuberculosis, there was a saying that nurses did not become infected with the disease. Williams, in 1878, reported no case of tuberculosis in twenty years among the attendants of the Brompton Hospital for Consumptives.¹⁰ At that time, however, nurses had no technical schooling. Recruited from the ranks of widows and older women, they constituted a miscellaneous and unsupervised group who had gained their skill through practical experience.

Today hospitals play an ever growing part in medical care and the role of nurse has passed from "neighbor women" to a specialized group trained during early maturity within the hospitals. Many hospitals have mandatory complete medical examinations of the nursing staff, and these examinations have established that while the incidence of tuberculosis among graduate nurses is low,¹³ among students it is apparently high. In evaluating this observation the crucial question is not how much tuberculosis exists in this group, but is there *more* tuberculosis among these students than among

comparable groups in other occupations.

The first problem is a consideration of how much tuberculosis exists among women of the age group of these student nurses, namely, 18-25. Although our first interest is morbidity, a study of mortality will give us important and more reliable information. Some statistics are recorded for the 20-30 age group, others for 20-25, we must use what is available.

Tuberculosis is the chief cause of death, and it accounts for 29 per cent of *all* the deaths that occur among *women* between 20-25 years of age (Fig 1A). I know of no reasons for expecting that the young women merely because they *choose* nursing as a profession will die of causes different from young women in general who are overtaken by an early death. We therefore *expect* that 29 per cent of all the deaths of student nurses in hospitals in New York City will be due to pulmonary tuberculosis.

It may sound *alarming* if we are told that the percentage of deaths from pulmonary tuberculosis is 40 per cent higher in some particular group of women than in men of the same age, but a comparison of A and B (Fig 1) will show that this is exactly what is to be expected for *any* group of women. Even more impressive is the statement that among student nurses the percentage of deaths due to pulmonary tuberculosis is three and one half times as high as that of adult population in general. Fig 1 shows that unless a course in nurses' training somehow increases immunity, this will be the case even though there is no tuberculosis hazard whatever in the nurses' occupation—that these facts exist because student nurses are women and are young. In other words, there is no evidence of

CAUSES OF DEATH - NEW YORK CITY FIVE YEAR PERIOD 1933-1937

FIG 1 When a woman between 20 and 25 dies the chances are nearly three to one that the cause of death is pulmonary tuberculosis

occupational hazard unless we find that more than 29 per cent of the deaths among student nurses are due to pulmonary tuberculosis

In the previous paragraph I have discussed the percentage of all deaths occurring between 20 and 25 years of age that are due to tuberculosis. Fig 2 shows us that the absolute number of deaths from pulmonary tuberculosis among women reaches a maximum in this same age range, making a peak far above the number of pulmonary tuberculosis deaths in any other group of women. The graph demonstrates that among women the higher the age the less probability of deaths from pulmonary tuberculosis. This explains, in part, the old dictum that "nurses do not get tuberculosis," because at the time that this idea prevailed, the nursing profession comprised an older group of women than it does today when students enter the training schools in their late teens. After 40 years of age, the mortality from pulmonary tuberculosis in females is

PULMONARY TUBERCULOSIS DEATH RATES FEMALES NEW YORK CITY 1920, 1933 AND 1937

FIG 2 The number of deaths from pulmonary tuberculosis is greater at 20-25 years than at any other age among women

two-thirds of that within the age group 20-25 (Fig 3) and the number of cases is one-third (Fig 2), for higher ages the decrease is still more striking. Consequently, if we compare the pulmonary tuberculosis of student nurses or any other group 18-25 years of age with that of groups containing appreciable numbers of older women, the 18-25 age group will show a higher incidence of pulmonary tuberculosis.

If there is a hazard from tuberculosis in an occupation, then the tuberculosis death rate in that group must increase. The tuberculosis death rate among women of the same age group as our student nurses is appallingly high. All institutions and industries employing young women must be prepared for this tragic situation. In reviewing reports, besides the fact that our age group has always had a higher mortality from tuberculosis than any other group of women, we must also bear in mind that twenty years ago the mortality rate at the ages 20-25 was 152 per 100,000 (Fig 3) and prior to that, it was even higher. In 1937 the mortality rate was only 56. The fact that nurses of twenty or thirty years ago had a higher mortality than young women generally today is no evidence of occupational hazard. It indicates solely

*Read at the Annual Meeting of the Medical Society of the State of New York,
Syracuse, April 25, 1939*

Not many groups have data as to the number of cases of tuberculosis. One such group comprises the employees of the New York Telephone Company, which maintains a diagnostic service including x-rays of the chest whenever there is any clinical indication. No pre-employment or periodic x-ray examination is made. Among the female employees between 20 and 30 years of age, the incidence of pulmonary tuberculosis has been found to be 0.9 per 1,000.⁸ The question for us to decide is whether this represents a reasonable basis of comparison with the incidence among pupil nurses. Can we properly state that if we find an incidence much in excess of 0.9 in the training schools that a tuberculosis hazard exists? Before this question can be answered, the efficiency of the case-finding procedure which established a morbidity of 0.9 among the telephone company employees must be compared with the efficiency of that used to determine morbidity among nurses.

The telephone company has no pre-employment nor periodic x-ray examinations. Nurses have both. It must be pointed out that while pre-employment x-ray examinations of the chest *reduce* the incidence of morbidity among an employed group where this examination is made, periodic examination *after* employment will certainly raise the reported morbidity. The extent of the increase or decrease which these two types of examination may cause in the reported morbidity of an employed group depends upon the type and thoroughness of the x-ray technic. It may also be influenced by the interpretation placed upon the x-ray findings—a mere suggestion of a shadow may mean refusal of employment or it may mean employment under observation while in some cases the candidate may be passed without question.

Where periodic x-ray examinations are used, many cases are found that ordinarily run their course without any clinical symptoms whatsoever, because "a large proportion of minimal cases re-

main minimal, and many of them do so in spite of violation of the standard rules of treatment" (Telford).¹⁷ A report by Myers, Ch'iu, and Streukens¹² is a recent illustration of this. In a series of 26 students who showed signs of pulmonary tuberculosis by x-ray, 3 had erythema nodosum, and 1 an elevation of temperature for a few weeks. It is unlikely that these 4 would have been found without the periodic x-ray examination and the other 22 would *certainly* have gone undetected because they had no clinical symptoms whatever. J. A. Miller⁹ speaking of lesions discovered by roentgenogram, says "In the great majority of cases these lesions are latent and innocuous and will always remain so under ordinary conditions of life." Such cases are the explanation of Stiehm's¹⁶ at first seemingly incredible statement that in fourteen years at the University of Wisconsin, with no case finding by x-ray, an average of 10 cases of pulmonary tuberculosis per year were discovered. During the first school year that periodic x-ray examinations were used, a total of 43 cases was found. This is an increase of 430 per cent over the fourteen-year average.

In view of these experiences one may predict a higher reported incidence of tuberculosis among nurses than among the telephone company employees, because of the difference in case-finding method. This group, therefore, cannot be compared with student nurses. We should seek as a basis of comparison a group that has had periodic x-ray examinations. However, it is rare to find any group of young women outside of hospitals who have periodic x-ray examinations. One such group, however, is that of the clerical employees of the Metropolitan Life Insurance Company Home Office, reported by Fellows² in 1934. These women all had pre-employment x-ray examinations and subsequent annual periodic re-examinations, mostly by fluoroscopy and a few by x-ray film. The incidence of pulmonary tuberculosis for the age group 20-30 was found to be 4.3 per 1,000, for ages 25-29

PULMONARY TUBERCULOSIS
NUMBER OF DEATHS
NEW YORK CITY 1933-1937^{inc.}

FIG. 3 The morbidity from pulmonary tuberculosis was much greater in past decades, but today, as in the past, the greatest number of cases among women is in the 20- to 25-year age group

that the mortality has declined in the last few decades. If 1,000 women students began a three-year course in domestic science on January 1, 1930, and you were informed that 4 of these died of tuberculosis within two years of graduation and 3 more died since, what would be your first reaction? If you examine the mortality statistics you will see that this is just what one may expect today. For a group of 1,000 students who began training in 1910 one expects to find that about 20 died of tuberculosis within seven years after graduation. These findings would hold for housewives, student nurses, or any other group of the same age. Having established a base line, let us examine such meager figures as are available.

Among 1,800 students nurses in the municipal hospitals of New York, part or all of whose training period fell between September, 1935, and September, 1938, there have been no tuberculosis deaths. Shipman and Davis¹⁵ reported 1 death in 1,240 nurses observed from one to nine years, Myers,¹¹ 2 in 215 students enrolled between 1929 and 1934 and observed until 1937, and Jones,⁶ 5 in about 1,400

nurses observed for five years. Amberson and Riggins¹ report no deaths among 492 nurses (about 807 life years). Other writers discuss morbidity without discussing mortality. We may assume that if there were any deaths at all in the series reported by these writers the number was insignificant, so that mortality, the most reliable index, does not indicate any serious occupational hazard.

I have omitted one author from the above statement, namely, Heimbeck,⁵ of Norway, whose observations began in 1920. He reports 14 deaths among nurses in 5,364 life observation years, a rate of 240 per 100,000, 10 of these 14 deaths occurred among 284 student nurses whose tuberculin test was negative on entering training. No such mortality is reported anywhere else in the literature, and certainly no such mortality exists in any American institution of today. Regardless of whether the figures correspond to our experience in this country, Heimbeck has made a great contribution in demonstrating that tuberculin-negative and tuberculin-positive students are two completely distinct groups in relation to the effect of tuberculosis exposure. It is this distinction that will be the basis for the solution of the problem of tuberculosis in nurses. In the municipal hospital the incidence of lung lesions among student nurses entering training with negative tuberculin tests was five times as common as among those tuberculin positive.

The question of occupational hazard has been investigated more often by morbidity studies than by studies of mortality. Morbidity statistics of tuberculosis are extremely difficult to compare, because standards determining a diagnosis of clinical tuberculosis or arrested tuberculosis or tuberculous infection change with each observer. In case of frank, well-developed tuberculosis, the comparison is simple, but we are dealing with early lesions. Recognizing this great difficulty, let us see if we can estimate the tuberculosis morbidity expectancy among women between 18 and 25 in New York City.

It is generally supposed that most of these primary infections take place in the lung. We have no way of demonstrating this except that in about 15 per cent of positive reactors, the primary tubercle in the lung with the surrounding tissue reaction casts a shadow on the x-ray film. This shadow may persist for months or years but eventually disappears, leaving a small nodule or fibrotic strand. These transient shadows of primary infection are difficult and at times impossible to distinguish from lesions which will progress and give symptoms. It follows that where there is an appreciable percentage of individuals who acquire allergy while under observation, the number of cases classed as pulmonary tuberculosis will be larger, but how much larger no one can say with certainty. That the primary lesion in the lung is *invariably* transient and uninfluenced by therapy, is not unanimously accepted, what is certain is that where you have many tuberculin-negative individuals you will find many of these primary lung lesions.

Though not quite of the same social economic level nor drawn from the same geographic communities, the most similar group to nurses is college students. The incidence of negative reactors in this group averages 35 per cent compared to about 50 per cent among the New York City student nurses. Among young women in colleges with periodic x-ray examinations for case finding, we find an incidence of 7.5 per 1,000.³

Geer,⁴ after stating that he finds a high incidence rate at Ancker Hospital, says "Gordon and Cashman, Norris and Landis, Ross, and others have expressed the belief that tuberculosis does not develop among nurses, doctors, and other employees who are working in tuberculosis institutions, but this is happening at Ancker Hospital, and it is stretching one's credulity too far to assume that in this respect Ancker Hospital is unique among American institutions."

The point is well taken. There is nothing different going on at one institution reporting a low tuberculosis inci-

dence and at another reporting a high incidence. What is happening is that each institution uses a different method of case finding or does no case finding at all, and each observer has his own standards of what candidates to exclude on first x-ray and what constitutes clinical pulmonary tuberculosis on subsequent examination. For example, Geer⁴ includes pleural effusion in his reported series, so that his incidence is not comparable with most statistics from which simple effusion is generally omitted. Among his cases he reports the following:

Case 4—Aged 21, entered training in September, 1929. Mother died of pulmonary tuberculosis in 1926. There was no reaction to 1 mg. of O.T. Physical examination was negative. Enrollment x-ray: small parenchymatous lesion in apex of right lung. Admitted to hospital in January, 1930 (four months after enrollment), because of loss of weight and fever in the afternoon. X-ray indications of tuberculosis increased, 3 plus to 0.1 mg. O.T.

It would never occur to me to include such a case of pre-existing lesion in a report of tuberculosis arising in the course of training. If we include such cases we must not compare the incidence with institutions that exclude these from their reports.

With more careful study and improved x-ray technic, I assume we shall find still more cases that we may class as clinical, secondary or primary, or arrested or healed, according to our standards. If we retest the negative tuberculin reactors and take more frequent films after they become allergic, we shall certainly find a much larger number of primary lesions. If we do, we must compare our incidence of cases found with other groups having similar, careful study and improved technic for case finding.

We must turn from the questions of morbidity, mortality, and positive x-ray films to consideration of the effect of primary infection in the adult. Most primary infections give no signs and no symptoms during any part of their course. We know of their presence in 85 per cent of cases solely by doing allergy tests. In the other 15 per cent there are, in

it was 6.1 per thousand. The peak in this group occurs a few years later than in most reports.

The combined effect of pre-employment examinations and case finding by annual fluoroscopic or x-ray examination is well shown by comparing the number of cases found among the insurance company employees and those found among the telephone company employees with no pre-employment x-ray of the chest and no periodic x-rays. The telephone employees do have an efficient diagnostic service that includes chest x-rays wherever there is the slightest clinical indication. Here we found a reported incidence of less than 1 in 1,000 for the age group 20-30. In other words, in 2 groups of women as nearly similar as can be obtained, both having good diagnostic service, the reported morbidity of tuberculosis is 475 per cent higher in the group given pre-employment and periodic x-ray examinations than it is in the group where no such examinations are made. The similarity to the 430 per cent increase in Stehm's¹⁶ series is no doubt a curiosity, but one that drives home the thesis of this paper, viz., the incidence of tuberculosis varies more with the method of case finding than all other factors of age, sex, and occupation put together.

If we were unaware of the clerical nature of the work done by the insurance company employees and had only these published statistics to go on, we could easily persuade ourselves that their occupation involves considerable hazard! In a large department store in New York City pulmonary tuberculosis among women, three-fourths of whom were under 30, was found to be 5.4 per 1,000 though only 1.6 were active. Less than half had periodic x-ray examinations. We, therefore, should expect *no lower* morbidity than 5 or 6 per 1,000 among student nurses.

The question for us to decide is "Should we expect a higher morbidity?" Naturally, we are now on guard as to the methods of case finding. Pupil nurses in municipal hospitals are examined by means of x-rays twice a year. Amberson

and Riggins¹ say "Tiny pulmonary lesions may appear and recede to insignificant dimensions within a year, and a semiannual roentgenogram will occasionally reveal one of these which would be missed by an annual fluoroscopy." This may raise our incidence but to what extent no one will know until a similar group of young women is x-rayed at the same intervals. We cannot guess how much higher the incidence would have been among the insurance company clerical employees if they had been x-rayed twice instead of only once a year, or if the department store employees had all been x-rayed, any more than any physician could possibly guess that an annual x-ray examination would uncover nearly five times as many cases of tuberculosis as the use of complete clinical facilities, exclusive of routine annual x-rays. All we may safely do is guess that the number of reported cases would be somewhat higher.

Another factor that may affect our morbidity comparison lies in the difficulty of differentiating between transient, primary infection, and an actively progressing lesion. A large proportion of the New York City pupil nurses come from small towns, while most clerical employees are residents of the city or suburbs. Consequently, among these nurses there is a much higher incidence of negative tuberculin reactors than among the insurance company employees. Mere residence in a crowded city would cause many of these negative reactors to become positive. Amberson and Riggins¹ in a tuberculin test in the largest of the five municipal hospital training schools included in the scope of this paper, found 48 per cent negative on entrance. The majority of these gave a positive reaction before the end of the three-year training course. Reports indicate that even in smaller cities, most of those who begin the nursing course with a negative tuberculin reaction acquire a primary infection as shown by allergy tests before graduation. Myers¹² reports about one-fourth positive on enrollment and more than 90 per cent positive on graduation.

It is generally supposed that most of these primary infections take place in the lung. We have no way of demonstrating this except that in about 15 per cent of positive reactors, the primary tubercle in the lung with the surrounding tissue reaction casts a shadow on the x-ray film. This shadow may persist for months or years but eventually disappears, leaving a small nodule or fibrotic strand. These transient shadows of primary infection are difficult and at times impossible to distinguish from lesions which will progress and give symptoms. It follows that where there is an appreciable percentage of individuals who acquire allergy while under observation, the number of cases classed as pulmonary tuberculosis will be larger, but how much larger no one can say with certainty. That the primary lesion in the lung is *invariably* transient and uninfluenced by therapy, is not unanimously accepted, what is certain is that where you have many tuberculin-negative individuals you will find many of these primary lung lesions.

Though not quite of the same social economic level nor drawn from the same geographic communities, the most similar group to nurses is college students. The incidence of negative reactors in this group averages 35 per cent compared to about 50 per cent among the New York City student nurses. Among young women in colleges with periodic x-ray examinations for case finding, we find an incidence of 7.5 per 1,000.³

Geer,⁴ after stating that he finds a high incidence rate at Ancker Hospital, says "Gordon and Cashman, Norris and Landis, Ross, and others have expressed the belief that tuberculosis does not develop among nurses, doctors, and other employees who are working in tuberculosis institutions, but this is happening at Ancker Hospital, and it is stretching one's credulity too far to assume that in this respect Ancker Hospital is unique among American institutions."

The point is well taken. There is nothing different going on at one institution reporting a low tuberculosis inci-

dence and at another reporting a high incidence. What is happening is that each institution uses a different method of case finding or does no case finding at all, and each observer has his own standards of what candidates to exclude on first x-ray and what constitutes clinical pulmonary tuberculosis on subsequent examination. For example, Geer⁴ includes pleural effusion in his reported series, so that his incidence is not comparable with most statistics from which simple effusion is generally omitted. Among his cases he reports the following:

Case 4—Aged 21, entered training in September, 1929. Mother died of pulmonary tuberculosis in 1926. There was no reaction to 1 mg. of O.T. Physical examination was negative. Enrollment x-ray: small parenchymatous lesion in apex of right lung. Admitted to hospital in January, 1930 (four months after enrollment), because of loss of weight and fever in the afternoon. X-ray indications of tuberculosis increased, 3 plus to 0.1 mg. O.T.

It would never occur to me to include such a case of pre-existing lesion in a report of tuberculosis arising in the course of training. If we include such cases we must not compare the incidence with institutions that exclude these from their reports.

With more careful study and improved x-ray technic, I assume we shall find still more cases that we may class as clinical, secondary or primary, or arrested or healed, according to our standards. If we retest the negative tuberculin reactors and take more frequent films after they become allergic, we shall certainly find a much larger number of primary lesions. If we do, we must compare our incidence of cases found with other groups having similar, careful study and improved technic for case finding.

We must turn from the questions of morbidity, mortality, and positive x-ray films to consideration of the effect of primary infection in the adult. Most primary infections give no signs and no symptoms during any part of their course. We know of their presence in 85 per cent of cases solely by doing allergy tests. In the other 15 per cent there are, in

addition, lung shadows on x-ray films. The assertion that tuberculosis is an industrial disease was originally based not on a greater incidence of clinical tuberculosis but on the fact that, of those who had a negative reaction on enrollment, a much larger proportion of pupil nurses acquired the primary infection than students in other professional schools or colleges.

When student nurses change from negative tuberculin to positive, though they are in no sense ill, they have acquired the potentiality of developing clinical tuberculosis. The overwhelming majority of mankind in the course of ordinary life activity acquires tuberculin allergy. This usually happens in childhood, but in the last two decades an increasing number of children do not acquire the primary infection. The question, whether a nurse who acquires this primary infection at the age of 20, rather than in her thirties, is more likely to develop clinical tuberculosis in later life, is one that cannot be answered with any finality. There is always the possibility that any nurse who in later life develops clinical tuberculosis would never have acquired her primary infection at all if she had not been a nurse in a hospital, she might have escaped that hazard.

Surveys of graduate nurses yield no greater number of positive x-ray findings than any other group of women. In x-raying 591 candidates (a younger group) for enrollment for nurses' training, Amberson and Riggins found 7, or 1.2 per cent, with pulmonary tuberculosis, this did not include calcified deposits in the parenchyma or tracheobronchial lymph nodes. Among the 5,000 graduate nurses in the municipal hospitals of New York City, the incidence is less than 0.5 per 1,000 per annum. Every other survey and all hospital experience show about this same incidence in graduate nurses, indicating that there is no more tuberculosis among graduate nurses than among other women. If this is correct, other women acquire that same hazard regardless of what occupation they follow.

We have then ascertained that the morbidity in training schools with semi-annual chest x-rays may not be compared with morbidity of groups who do not have such periodic examination. The incidence of tuberculosis found in other groups will vary from 0.9 to 7.5 for each thousand observation years, depending on the thoroughness and frequency of the examinations.

In five of the seven nurses' training schools connected with the municipal hospitals of the City of New York, there were 1,800 pupils in training for periods varying from a few months to three years between September, 1935, and September, 1938. Twenty cases of pulmonary parenchymal tuberculosis were found by periodic examinations of girls whose first x-rays showed no lesions or only a primary complex. I have not included 5 cases of pleurisy with effusion if they have never (before or after) developed a parenchymal lesion. Such cases are not included in the insurance company or telephone company statistics or most other reports of pulmonary tuberculosis. This gives an annual incidence of 6.9 per 1,000, which is 50 per cent higher than that of the clerical employees of the insurance company of the same age and 10 per cent higher than the clerks 25-29 years of age.

Amberson and Riggins in Bellevue Training School alone, in five years, 1931-1936, found 6 pulmonary lesions, 1 tuberculous spondylitis, and 1 pleurisy (serofibrinous). The 6 parenchymal lesions give an annual incidence of 7.4 per 1,000.

The numbers given in reports on student nurses are too small for any but temporary conclusions. Can we conclude that more pulmonary tuberculosis is present among these student nurses (reported 6.9 per 1,000) than among the clerks of the insurance company (reported 4.3 for 20-30 and 6.1 for 25-30 age group)? Or does this increase in reported incidence bear a similar relation to differences in examination methods, which is responsible for the increase of 470 per cent over the telephone company when

compared with the insurance company and due to the difference in examination methods between these two companies? Is it analogous to the 600 per cent difference between the telephone company and a department store? How much of this 30 or 50 per cent increase is due to finding the transient, benign shadows of primary tuberculosis in the lungs? Why do we find reports of greater incidence (7.5) among college students than among nurses?

I have not attempted to answer these questions but have limited this paper to presenting data for the purpose of indicating that the answers must be made with care. Hasty conclusions have been published. They are likely to lead us to false generalizations on the epidemiology of tuberculosis with disastrous effects on progress in prevention and in therapy. The conclusion we may draw is that comparison of the nursing group as a whole to other groups does not indicate that tuberculosis is an occupational disease. Before we may make any positive generalizations from this negative statement we must divide nurses into those with primary infections (tuberculin positive) and those without primary infections (tuberculin negative). Because practically every graduate nurse is tuberculin positive, our studies must concentrate on the student nurses. We know that tuberculin-negative student nurses almost all acquire the primary infection before the end of the three-year training period. The indications are that among those students originally tuberculin positive the incidence of lung lesions is far less than the expectancy at that age and for tuberculin negative the incidence is greater than the expectancy.

Summary

1 The percentage of all deaths due to pulmonary tuberculosis in the age group in which student nurses belong is higher than in any other age sex group (Fig 1)

2 The number of deaths due to pulmonary tuberculosis is greater at this age than at any other (Fig 2)

3 The morbidity of pulmonary tuberculosis is higher at this age than at any age among women (Fig 3)

4 Periodic x-ray examinations increase the number of pulmonary lesions found among young adults by as much as 475 per cent

5 Nurses' training school classes contain a large number of girls from small towns who are tuberculin negative, such a group will show a number of cases of lung shadows of primary tuberculosis which would never have been known except for the routine x-ray films. These shadows are not usually clinical tuberculosis, but do swell the *reported* morbidity for the group

Conclusion

Every study of tuberculosis among nurses must take into consideration (1) the difference between tuberculin-negative and tuberculin-positive individuals, (2) the statistics on tuberculosis morbidity and mortality which serve as a basis for comparisons

Illinois M. J.

THE SPASMOGENIC TENDENCY AND ITS RELATION TO THE EYES

ROBERT K. LAMBERT, M.D., New York City

A GREAT many patients come to the ophthalmologist for disturbances that do not lend themselves to strictly pathologic analysis. These ocular disturbances manifest themselves by varying types and degrees of pain, discomfort, and interference with function. In the absence of any organic disease most of the pain and distress arise in the smooth muscles of the eyes. It is frequently difficult to draw the line between so-called "asthenopia" and hypertonicity of the accommodative mechanism. The patient who has "weak eyes" and is incapable of sustained ocular effort, generally experiences pain, burning, or some type of discomfort after a certain amount of use. These symptoms, in the absence of pathologic changes, may be due to compensatory muscular efforts, necessary for some particular reason, and are avoided by not allowing the eye muscles more than a low threshold of work. Identical symptoms may be produced in uncorrected ametropic eyes working for short periods of time and emmetropic eyes doing work under adverse conditions or for longer periods of time.

Of course, a great many local factors exist, and it is the aim of the ophthalmologist to cure as many patients as he can by the correction of refractive errors and other relatively simple measures. Fortunately in a large percentage of instances, particularly ametropia, these measures are effective. Furthermore, from time to time more mechanical defects are disclosed, such as differences in image size, enabling the ophthalmologist to include more patients in the group he can assist by optical means.

After many attempts to correct local causes have been made, there still remain patients whose accommodative mechanism

gives evidence of violent response to minimal stimuli, or in other words, who have insufficient anatomic basis for their ocular disturbances. This group appears to have a tendency toward spasm of the smooth musculature of the eye.

It has long been an established fact that certain individuals are subject to various types of smooth muscle spasm. The pathophysiology of tonic, cramplike, smooth muscle contractions, whether in a hollow viscus, blood vessel, or the iris and ciliary body, follows certain patterns and responds to certain forms of therapy. The bronchioles, bladder mechanism, and all parts of the digestive tract are common sites of smooth muscle spasm. Certain disturbances such as coronary disease and essential hypertension are still of questionable nature, although there is reason to believe that the underlying nature of the condition is smooth muscle spasm of the vascular system.

General Aspects

Let us first consider the general aspects of persons who have "the spasmogenic aptitude" of Houston, after which we can consider the factors that predispose toward ocular spasm in particular.

Certain types of individuals apparently are subject to smooth muscle spasm. There are (1) sensitive, high-strung people in particular environmental difficulty, such as highly competitive or overactive work, (2) psychoneurotics, (3) individuals temporarily depressed through fatigue or habits injurious to them, (4) allergic or drug-sensitive individuals.

There is a very difficult line to be drawn between sensitive individuals confronted by a difficult or highly competitive environment so common today and psycho

neurotics who are constitutionally unable to face the realities of life. Houston has pointed out that oriental races which face their problems, either objective or subjective, with a calm placid acceptance, are practically never the victims of smooth muscle spasm. They have neuroses, but the physical manifestations are differently expressed. Essential hypertension and other manifestations of spasm are virtually unknown to the Chinese. Conversely, our Western civilization, which places a premium on aggressively meeting and overcoming obstacles, is apt to produce individual reactions of a spastic nature. As I have said, it would not be difficult to cite numerous instances from general medicine, such as cardio-spasm, psychogenic asthma, and spastic constipation, but enlarging upon this subject would take us too far afield.

The philosophic implications of these relationships, while being fascinating to a degree, are not particularly relevant to this presentation. The relationship of fatigue or weakness to spasm is that of a compensatory effort that overshoots the mark and produces a cramplike response. Allergic manifestations are notably twofold: changes in capillary permeability with edema, and smooth muscle spasm. One familiar example of the latter is asthma in individuals sensitive to inhalants.

I do not wish to be misunderstood, or to minimize in any way the importance of the local causes of asthenopia, whether the patient can be included in the foregoing groups or not. In most instances any tendency toward a persistence of smooth muscle spasm in the eyes can be averted by proper local therapy. Relieving a convergence insufficiency, an early presbyopia, or any of the manifold disturbances that result in eyestrain, will generally be enough to stop the symptoms.

The troubling cases, however, are those in which the symptoms are out of all proportion to the ocular causes, and persist after these causes have been corrected. In my experience it is most unusual to have persistent irritability of the

intrinsic eye muscles, without any local imperfection to direct the channels of reflex spasm toward the eye. While such cases do occur, generally the spasms are only manifested in the more vulnerable parts of the body. Most of the patients who have shown irritability of the intrinsic eye muscles have had a definite *locus minoris resistentiae* of the eyes, in addition to falling into one of the previously mentioned groups. These patients for the most part have had repeated refractions with many slightly different corrections and innumerable general examinations to find some particular cause for their inability to use their eyes with comfort. The syndrome presented is therefore as follows: the individual usually has some inherent eye defect or refractive error. He is unable to use his eyes normally despite the proper correction because of pain or discomfort, and there is an apparent hyperirritability of the ocular smooth muscles. A ciliary blush or a low-grade iritis may occur at any time. Measurable accommodative spasm, preceding a manifest myopia, may even be present. In addition there are generally parallel spastic symptoms, such as spastic constipation, in other parts of the body.

Treatment

We can assume that in every case there has been a search for correctable local defects. Whether or not a patient has a "spasmodic aptitude" is of no special interest to the ophthalmologist if he can eliminate ocular distress by corrective lenses or orthoptic training.

Some patients, however, can never hope for perfect optical corrections. Their weak point is a residual anisometropic error, muscle imbalance, or other defect. Under ideal conditions these patients may function normally with full use of their eyes. If another factor arises, such as general fatigue, anxiety, or even the excessive use of tobacco, there is an effect upon the autonomic nervous system, and smooth muscle irritability may result. A local approach may be adequate for this type of patient. One must approach the

problem as though no anatomic defect were present at all. Great loss of time and effort can take place in these cases by overstressing the mechanical situation and by repeated examinations. This local overattention may even aggravate the tendency toward spasm. The basis of the trouble can frequently be disclosed by careful history taking.

The patient's habits must first be considered. Insufficient rest should of course be remedied. If the environment is such as to exert pressure on the individual, he should be taught, as far as one is able to teach relaxation, not to make pressure upon himself. The eyes should be used in a consciously relaxed manner and not with the peering and wrinkled brow indicative of intense concentration.

The effect of tobacco is marked in aggravating a spasmogenic tendency. The exact nature of the mechanism is in doubt, although the effects are beyond question. The recent work from the Mayo Clinic by Cusick and Herrell on the effect of tobacco on the retinal arterioles is of interest in this connection and may indicate a hypersensitivity in certain individuals. Strangely enough, alcohol is much less of an offender in this particular respect. It even may be helpful in relaxing the individual and providing an easier adjustment to his environment.

As said before, one of the characteristic allergic responses of the body is smooth muscle spasm, so it may be wise to eliminate common allergens from the diet of known allergic sufferers. Even allergic studies may be indicated.

The treatment of psychoneurotics must be worked out for each individual case. In not all of these is there a definite spastic tendency, some individuals showing simple anxiety over the use of their eyes or an overprotectiveness. This particular subject is of great importance clinically, and it is surprising how little attention it has received in the ophthalmologic literature. The only recent papers to my knowledge are those of C W Rutherford in 1932 and George Derby in 1930. In general it would seem wise for the ophthalmologist to avoid any ex-

tensive investigation of his patients along psychiatric lines. Such a procedure by one not properly trained for the work is apt to produce more harm than good. Recognition of the condition and perhaps encouragement and suggestion or substitution therapy are indicated, however. When the patient is sufficiently intelligent, proper psychotherapy in the hands of an expert is of inestimable value. It is interesting that in former days sea voyages were frequently ordered in cases with persistent eyestrain. One wonders to what extent this method worked by removing the patient's responsibilities and relieving his anxieties.

The use of antispasmodics is frequently effective. Tincture of belladonna by mouth seems a good drug for general use and may be tolerated in large doses. The best method is to give quantities up to the production of slight toxic effects, such as dryness of the mouth. I shall not deal extensively with the local use of mydratics as most ophthalmologists have individual preferences. It is, however, more convenient and comfortable for the patient if he can maintain proper function of the eyes without resorting to cycloplegia or premature presbyopic corrections. Certain drugs combine the properties of both antispasmodic and sedative, and in certain cases, where anxiety or worry seems to be the chief factor in upsetting the patient's equilibrium, small doses of a simple sedative such as phenobarbital or chlorbutanol may be most helpful.

Case Reports

Case 1—L. R., male, aged 45, physician engaged in active practice, was almost completely unable to read for more than a few minutes at a time because of severe headaches and eyestrain. The patient had acquired, in the course of several years, at least a dozen corrections for an anisometropic error. These corrections were given by competent ophthalmologists. His general health was good save for spastic constipation and a fissure in ano. The patient was a fairly heavy smoker, consuming many cigars and a pack of cigarettes a day. Very little change was made in the patient's correction but he was asked to eliminate

tobacco and use tincture of belladonna gtt's 10 three times a day. The function of his eyes began to improve within a few days. While this patient never can be expected to have a very high tolerance for sustained ocular effort, it is now possible for him to do an adequate amount of reading. By rest and the use of tincture of belladonna he can even abort attacks of pain and headache. Conversely, smoking particularly cigars, is almost invariably followed by a period of ocular discomfort.

Case 2—R. S., female, aged 38, high-strung, irritable housewife, had been wearing a low myopic correction with slight alterations for some years. She had had much difficulty in using her eyes at motion pictures and for reading and writing. The maximum amount of comfort was obtained several years previous by the use of bifocals with additional correction for near work. Despite this help, reading for more than a few minutes produced pain in the eyes and forced her to stop. The patient herself desisted from smoking several years ago as it disagreed with her. She was referred back to her family physician and put on tincture of belladonna gtt's 10 three times a day. Although she was greatly helped and could read, there were numerous neurotic manifestations in addition to her reading disability and it was thought wise to send her to a psychiatrist for study. Psychoanalysis was resorted to and marked improvement was obtained after the underlying neurotic factors in the case were understood. She is able now to use her eyes almost normally, without any excessive discomfort.

Case 3—N. D., female, aged 28, high-strung, hypersensitive secretary. Patient's symptoms dated back to ten years ago when she was struck by an automobile and suffered from shock. She had been wearing a low hyperopic correction previous to the accident. Shortly after the accident, the patient began to complain of headaches, constipation, digestive disorder, and discomfort when using her eyes for the ten days previous to the onset of her menstrual period. There was also a great deal of discomfort during the first twenty-four hours of menstruation. These symptoms have persisted to the present.

About one year ago, the discomfort when using her eyes became more marked and several slight changes were made in her correction.

During the ten days preceding menstruation the patient uses a plus 0.50 sphere added to her correction and tincture of belladonna gtt's 10 three times a day. The patient is symptom-free after menstruation ceases. She has been examined by a gynecologist who states that there

is no pelvic disorder responsible for her symptoms, so that the condition may perhaps be classified among the traumatic neuroses with conversion symptoms to various parts of her body. The condition, however, is not severe enough to warrant psychiatric treatment.

Conclusion

It has long been recognized by ophthalmologists that measurable accommodative spasm associated with ocular discomfort and visual disturbance does exist. The recognition of subclinical and low-grade forms of this particular type of disordered function has not been so general. While it has also been well recognized that there are various forms of smooth muscle response in different parts of the body to anxiety, emotional disturbances, and various forms of allergy, this particular syndrome has not been so clearly defined in relation to the ocular mechanism.

Many factors are still poorly understood concerning smooth muscle spasm, and it is hoped that the psychosomatic approach will make treatment for this group more effective by the ophthalmologists. We need not limit ourselves in this respect to so-called "functional disturbances," for as Fremont-Smith says "Organs and tissues which are the site of disease are not immune to the physiological and biochemical effects of emotional conflict." There can be no doubt that the psychosomatic approach will be of fundamental importance to the future of medicine, as evidenced by Dunbar's comprehensive survey of the literature.

Discussion

Dr. Charles A. Perera, *New York City*—Dr. Lambert has reminded us that treatment of local symptoms without adequate study of the personality and organism of the patient as a whole may be to fail in our function as physicians.

With the modern emphasis on specialism in all fields of medicine and on the mechanistic approach to disease, the psychic component has often been overlooked or slighted. The essayist has touched upon an aspect of ophthalmology which is of immense clinical importance.

The role of the emotions upon the autonomic nervous system, and its resulting smooth muscle spasm of all types and gradations is being increasingly recognized in such diseases as essential hypertension, angina pectoris, bronchial asthma, cardiospasm, pylorospasm, spastic constipation, bladder disturbances, and glaucoma. Many patients are suffering from less well-defined pathologic states of psychogenic origin and also belong to the group possessing the "spasmogenic aptitude." The patients cited by Dr. Lambert have a lowered threshold of sensitivity, and react excessively to stimuli which do not ordinarily affect normal individuals.

Ocular symptoms in these patients are due to external causes focused upon an organ of psychically lowered resistance. Since the eyes play a predominate part in the individual's contact with the outside world, they are often affected in patients who have problems or conflicts which they cannot face or do not wish to meet. Fear of injuring the eyes or of losing eyesight is often productive of ocular complaints which are relieved when the fear is removed. Blepharospasm is frequently on a psychogenic basis, the patients with this disability being unwilling to face or open their eyes to a situation which they cannot handle or wish to avoid. Eye symptoms may develop from a desire to escape from an intolerable situation, even to the ultimate stage of hysterical amblyopia. Patients may use their ocular complaints to avoid work, emotionally elaborating upon a slight physical basis. Symptomatic therapy in these instances without psychotherapy may be ineffective or even harmful.

In dealing with the patient with a spasmogenic tendency, a complete history should be taken, and the examination should include a study of the sufferer as an individual, and not, as is too often the case, as an optical and ocular motor mechanism. The treatment of patients with photophobia, burning sensation in the eyes, difficulty in reading for more than a short time, and aching pains in and around the eyes, and with no uncorrected defects, should include correction of faulty habits of life, avoidance of fatigue and anxiety and other factors productive of smooth muscle spasm, the use of sedatives and antispasmodics, and the elimination of local irritation. Most of these patients have a local hyperemia and thickening of the conjunctiva,

and a surprising number are benefited by treatment with the copper sulfate stick applied to the palpebral conjunctiva of the lower lid and of the inner and outer portions of the upper lid, followed by copious irrigation with saline or horic solution. It is impossible to say how much the efficacy of this form of treatment depends upon suggestion and how much depends upon amelioration of the conjunctival sensitivity to minimal stimuli. Local treatment must be accompanied by a sympathetic handling of the patient's fears and worries.

I believe that the ophthalmologist, as well as other physicians, should be trained in the investigation of his psychoneurotic patients should collaborate with the family doctor, and, if need be, with the psychiatrist.

Dr. Lambert's paper has opened up for our study an interesting field which is more vast than we suspect, which includes many baffling problems, and which will lead to new conceptions in the realm of diagnosis and treatment in our specialty.

Dr. Harold Van Lammers, *Flushing, New York*—Dr. Lambert is to be congratulated, not so much in that he has brought us a classification of what we prefer to call "trouble cases," but that he has had the ability to keep these persons under his care long enough to obtain data of value.

I should like to confine my discussion to the type of headache which is a prominent part of this person's complaint. This headache is not quite the usual one registered by the astigmatic patient, or the one with muscle defect, or size image defect. It is a type that we are likely to overlook or assign to other causes, the most frequent being that of low activity glaucoma or sinus disease.

The typical headache starts off with discomfort of the eyes on application even after a few minutes. However, it quickly reaches its maximum so that the patient can continue his work despite the headache and it becomes no more intent. However, most of these persons so afflicted can no longer concentrate and with the discomfort, discontinue their reading. The intelligent patient, however, quickly correlates the intense distressing headache which he experiences on arising in the morning with his reading of the night before. This ache is over the eyes and the sides of the brow. At times, it may be knife-like and sharp and is described as "cutting flashes," and usually lasts but short periods and at intervals. However, the dull depressing ache continues until about noon when the head begins to clear and provided this person does no clerical work he again feels capable of intense effort. The pa-

tient soon learns, however, that he is not to use the eyes in the morning or the ache is prolonged

Several diagnostic observations may be noticed by this person. He soon learns that if he reads the night before he will have headaches in the morning. The same holds true for going to the movies. He knows also that if he goes to bed early and sleeps late he will have the headache on arising. He also knows that if he goes to bed late and gets up early his headache is less intense if at all. At no time does he have nausea unless it is coincidental from some other cause.

Needless to say many such persons applying for aid give as accurate a history as I have described. He is likely to lead the physician into believing that this ache is secondary to sinus infection or obstruction. However, this is easy to find out by regulating the use of the eyes from which source the headache is derived.

Over the weekend, this person usually does not have headaches. If Dr. Lambert has ever taken a sea voyage he certainly realizes that a good deal of his time must be spent in reading due to the lack of facilities for exercise or other occupations of interest. In my opinion, a land voyage is much to be preferred as distant gaze results in little discomfort.

To me it seems reasonable that this headache should come on in the morning. When a football player gets an acute traumatic myositis he often at the time does not realize the injury but when the thigh muscles begin to relax the following day he then has pain and discomfort. He knows that this pain can be eliminated by producing spasm of the muscle and all of us have seen players arising from the bench forcefully striking their thighs with their fists to produce muscle spasm eliminating the pain. The following day as the muscle relaxes, the pain is even then more intense. He requires complete rest rather than whipping the injured muscle to renewed activity to eliminate the complaint.

When does the patient with a tuberculous hip infection have pain? Not when the muscles of the hip are contracted but when they are relaxing so that often the worst pain is at night or at early morning. Dr. Lambert mentions spasm of the smooth muscles, but I wonder if striped muscles do not make themselves evident on relaxation also.

To successfully treat a troubled case of this kind, it is necessary to gain such confidence of your patient that he will remain continuously under your care. All defects must be corrected, and his life so regulated to permit him fifteen minutes of reading a day. In this way, this

person will not be overcome by the apparent necessities of life and can successfully cope with his or her environment.

Dr. Macy L. Lerner, Rochester, New York—Dr. Lambert's paper has great value for us. He calls our attention to a certain group of patients who cannot be relieved by the most painstaking refraction and yet it is our problem to solve their difficulties. If we consider that most of our work is refraction and that a large number of patients with apparent refractive symptoms do not need glasses, a careful study of these problems is worth while.

I recall a lady asking me, "Doctor, don't you tire of examining for glasses all day long, doing the same thing over and over?" My reply, of course, was that I do tire, but that every case is different, not in spheres and cylinders, but in the solution of each patient's problems.

You have to be some sort of a G man to learn which smooth muscle fibers in the body are the actual offenders, whether ciliary, genital, intestinal or sexual. My feeling is that there must be a central station from which messages are relayed to these smooth muscle fibers. These patients belong to general medicine. The physician in charge should study these patients carefully, the ophthalmologist's task is advisory. To administer tincture of belladonna for the relief of symptoms appears to me to be only a part of the treatment. I became interested in the subject about eight years ago when I had the opportunity to read a paper on ocular neurosis. At that time I referred to the article by the late Dr. Derby of Boston which Dr. Lambert has mentioned. Since then my hobby has been to lecture once a year in our graduate course in Ophthalmology on a similar subject. The title I have preferred is "Refraction, a Medical Problem." It seems to me this broader term would include not only this group of spasmogenic cases but many other problems closely related to it. I believe a patient with spasmogenic tendency in the eyes deserves a study with particular attention to the ocular muscle balance. A very careful approach must also be made in taking not only the ocular history but the general history. If the patient finds the ophthalmologist sympathetic and willing to listen, a great deal can be learned which will help in the management of his problem.

I wonder whether the case cited by Dr. Lambert in which a patient obtained complete relief by taking tincture of belladonna and eliminating cigarettes may not have some other factors responsible for the symptoms. I note that the patient had a marked degree of anisometropia.

With the modern emphasis on specialism in all fields of medicine and on the mechanistic approach to disease, the psychic component has often been overlooked or slighted. The essayist has touched upon an aspect of ophthalmology which is of immense clinical importance.

The role of the emotions upon the autonomic nervous system, and its resulting smooth muscle spasm of all types and gradations, is being increasingly recognized in such diseases as essential hypertension, angina pectoris, bronchial asthma, cardiospasm, pylorospasm, spastic constipation, bladder disturbances, and glaucoma. Many patients are suffering from less well-defined pathologic states of psychogenic origin and also belong to the group possessing the "spasmogenic aptitude." The patients cited by Dr Lambert have a lowered threshold of sensitivity, and react excessively to stimuli which do not ordinarily affect normal individuals.

Ocular symptoms in these patients are due to external causes focused upon an organ of psychically lowered resistance. Since the eyes play a predominate part in the individual's contact with the outside world, they are often affected in patients who have problems or conflicts which they cannot face or do not wish to meet. Fear of injuring the eyes or of losing eyesight is often productive of ocular complaints which are relieved when the fear is removed. Blepharospasm is frequently on a psychogenic basis, the patients with this disability being unwilling to face or open their eyes to a situation which they cannot handle or wish to avoid. Eye symptoms may develop from a desire to escape from an intolerable situation, even to the ultimate stage of hysterical amblyopia. Patients may use their ocular complaints to avoid work, emotionally elaborating upon a slight physical basis. Symptomatic therapy in these instances without psychotherapy may be ineffective or even harmful.

In dealing with the patient with a spasmogenic tendency, a complete history should be taken, and the examination should include a study of the sufferer as an individual, and not as is too often the case, as an optical and oculomotor mechanism. The treatment of patients with photophobia, burning sensation in the eyes, difficulty in reading for more than a short time, and aching pains in and around the eyes, and with no uncorrected defects should include correction of faulty habits of life, avoidance of fatigue and anxiety and other factors productive of smooth muscle spasm, the use of sedatives and antispasmodics, and the elimination of local irritation. Most of these patients have a local hyperemia and thickening of the conjunctiva

and a surprising number are benefited by treatment with the copper sulfate stick applied to the palpebral conjunctiva of the lower lid and of the inner and outer portions of the upper lid, followed by copious irrigation with saline or boric solution. It is impossible to say how much the efficacy of this form of treatment depends upon suggestion and how much depends upon amelioration of the conjunctival sensitivity to minimal stimuli. Local treatment must be accompanied by a sympathetic handling of the patient's fears and worries.

I believe that the ophthalmologist, as well as other physicians, should be trained in the investigation of his psychoneurotic patients, should collaborate with the family doctor, and, if need be, with the psychiatrist.

Dr Lambert's paper has opened up for our study an interesting field which is more vast than we suspect, which includes many baffling problems, and which will lead to new conceptions in the realm of diagnosis and treatment in our specialty.

Dr Harold Van Lammers, *Flushing, New York*—Dr Lambert is to be congratulated, not so much in that he has brought us a classification of what we prefer to call "trouble cases," but that he has had the ability to keep these persons under his care long enough to obtain data of value.

I should like to confine my discussion to the type of headache which is a prominent part of this person's complaint. This headache is not quite the usual one registered by the astigmatic patient, or the one with muscle defect, or size image defect. It is a type that we are likely to overlook or assign to other causes, the most frequent being that of low activity glaucoma or sinus disease.

The typical headache starts off with discomfort of the eyes on application even after a few minutes. However, it quickly reaches its maximum so that the patient can continue his work despite the headache and it becomes almost more intent. However, most of these persons so afflicted can no longer concentrate and, with the discomfort, discontinue their reading. The intelligent patient, however, quickly correlates the intense distressing headache which he experiences on arising in the morning with his reading of the night before. This ache is over the eyes and the sides of the brow. At times, it may be knife-like and sharp and is described as 'cutting flashes' and usually lasts but short periods and at intervals. However the dull depressing ache continues until about noon when the head begins to clear and, provided this person does no clerical work he again feels capable of intense effort. The pa-

CAMP SANITATION

C. A. HOLMQUIST, Albany, New York

(Director, Division of Sanitation New York State Department of Health)

THE supervision over camps, although relatively new, is one of the major public health problems confronting state health departments today. The importance of the problem is indicated by the fact that in New York State alone there are approximately 3,000 camps occupied by from 2,000,000 to 3,000,000 persons a year and that a number of outbreaks of preventable disease occur in these camps each year.

New York was one of the first states to assume control over the sanitary condition of camps when in 1914 the newly established Public Health Council enacted Chapter V of the State Sanitary Code governing labor camps, there having been a number of outbreaks of water-borne disease attributed to the pollution of water supplies derived from watersheds occupied by such camps. At that time there were relatively few organized summer camps in the state and their supervision was not yet considered a serious problem. Consequently, Chapter V of the Sanitary Code was drawn up primarily to protect the public from unsanitary conditions arising from the operation of labor camps. This code prohibited any person from establishing or operating a labor camp without a permit from the local health officer and contained few regulations except those relating to the control of communicable diseases and the minimum distances which buildings of labor camps and more particularly sources of pollution may be maintained from lakes, ponds, streams, and sources of public water supply.

The urge to live outdoors and the rapid growth in automobile transportation enabling people to penetrate to the remotest parts of the country led to the establishment of numerous organized

summer camps for both children and adults and more recently the so-called "tourist" camps. Such organizations as the Boy Scouts, Girl Scouts, Y M C A, Y W C A, realizing the advantage from the standpoint of health, recreation, and character building of having children and young people live in the open under trained leadership for various lengths of time during the summer months established many summer camps throughout the country.

The inspection by this Department of some of the first summer camps established indicated the urgent need for the supervision over the sanitary conditions not only of labor camps but also of summer camps. Consequently, the Public Health Council on May 15, 1924, so amended Chapter V of the Sanitary Code as to apply to any camp or tract of land on which ten or more persons may camp, either free of charge or by the payment of a fee. In 1932 and again in 1935 the Sanitary Code relating to camps was so amended as to protect more adequately not only the public but more particularly the health of the campers.

In the last revision a camp was defined "to mean one or more temporary or permanent tents, buildings or structures, together with a tract of land pertaining thereto, established or maintained as living quarters for temporary occupancy by ten or more persons, including children, either free of charge or by the payment of a fee." This definition was designed to cover not only labor and summer camps but also most house-trailer camps and tourist camps having five or more cabins, assuming that each cabin could be occupied by two persons.

Our investigation of many of the summer camps established before the camp

Was he given the benefit of the latest ideas regarding the possible existence of aniseikonia? This itself would play a considerable part in his symptoms. Furthermore, there is a history of

fissure in ano and spastic constipation. If you have suffered from either of these you will appreciate that it may produce referred symptoms

VENEREAL DISEASE QUACKERY GROWING

Venereal disease quackery is on the increase and today constitutes one of the major obstacles to the public health control of syphilis and gonorrhea, officers of the U S Public Health Service state in a nationwide N B C broadcast.

Drugstore "back counter prescribing" has increased substantially during the past several years. Many different "patent remedies"—produced both locally and on a national scale—are on the market and sold in large volume. There is indication that the sales curve has been rising during the past six or eight years.

Large numbers of unethical practitioners—"men's specialists," herbalists, mail-order experts—are active, although quack advertising has apparently decreased in volume.

More persons evidently are going to drugstores and quacks for diagnosis and treatment of venereal disease than are going to reputable physicians. Exploitation of persons who are, or think they are, sick with gonorrhea or syphilis runs into tens of millions of dollars annually.

These trends were reported in a survey conducted by the American Social Hygiene Association in cooperation with the U S Public Health Service ("Illegal and Unethical Practices in the Diagnosis and Treatment of Syphilis and Gonorrhea," by Mary S Edwards, statistician, and Paul M Kinsie, chief of field study, of the American Social Hygiene Association, published in the January, 1940, issue of *Venereal Disease Information* of the Public Health Service).

Personal interviews by trained investigators posing as "friends" of presumably infected persons were carried on in 1,151 drugstores in 30 cities in 26 states. Sixty-two per cent of the drugstores visited diagnosed the diseases and offered to sell remedies for alleged syphilis or gonorrhea, especially the latter. Thirty-one per cent did not attempt to diagnose, but stocked, and were willing to sell, bottled remedies, especially when asked for them by name. About half of those who sold remedies urged the inquirer to see a doctor. Only 7 per cent of the entire number refused to diagnose or sell remedies.

About 30 different preparations were found to be generally available as remedies throughout the nation. Only 3 or 4 were recognized drugs, the remainder consisting of completely worthless mixtures as far as any effect on syphilis or gonorrhea was concerned. Mixtures made from such ingredients as boric acid, berberin, glycerin, etc., of only a few cents value are sold at prices ranging from \$1.00 to \$3.00 a bottle.

GENIUS AND THE JITTERS

All great works in the world are done by neurotics, Dr Nolan D C Lewis, professor and executive officer of the Department of Psychiatry of the College of Physicians and Surgeons, Columbia University, told an audience at the American Institute, 60 East Forty-second Street, New York City, on January 9, as reported in the New York *Herald-Tribune*. Normal persons, those of exemplary conduct in every respect, he said, remain mediocrities.

"I'm not interested in normal people," Dr Lewis said, and then he related experiences with some famous neurotics who wanted to be cured of their neuroses but retain their genius.

"A very famous woman novelist came to consult me not long ago about her neurosis," related Dr Lewis. "I recognized her trouble and I told her I could cure her but that she would no longer write novels if I did. She of course, desired treatment, but I decided that it would be a pity to destroy a fine novelist and so I refused to cure her, and she is continuing to write fine novels. If I had cured her, all the mystery that she puts

into her novel-writing would have been destroyed."

Dr Lewis then told of his experience with a famous pianist. "He came to me and asked to be treated for his trouble. I warned him that I could cure him, but that he might never play the piano again. He begged me to go ahead and cure him. Well, I have cured him, but he is no longer a great artist of the piano. He is now a fine mathematician."

Dr Lewis related a final instance of a well known magazine illustrator who sought treatment for his neurotic difficulties. This painter was also cured of his neurosis, the physician said, but he lost his fine artistry with the brush and has now become one of the city's best known photographers.

"It is true," concluded Dr Lewis in reply to a question "that we know that neuroses produce works of genius, but we do not yet know how to produce these neuroses artificially, nor how to direct them and so create geniuses or works of genius."

CAMP SANITATION

C A HOLMQUIST, Albany, New York

(Director, Division of Sanitation, New York State Department of Health)

THE supervision over camps, although relatively new, is one of the major public health problems confronting state health departments today. The importance of the problem is indicated by the fact that in New York State alone there are approximately 3,000 camps occupied by from 2,000,000 to 3,000,000 persons a year and that a number of outbreaks of preventable disease occur in these camps each year.

New York was one of the first states to assume control over the sanitary condition of camps when in 1914 the newly established Public Health Council enacted Chapter V of the State Sanitary Code governing labor camps, there having been a number of outbreaks of water-borne disease attributed to the pollution of water supplies derived from watersheds occupied by such camps. At that time there were relatively few organized summer camps in the state and their supervision was not yet considered a serious problem. Consequently, Chapter V of the Sanitary Code was drawn up primarily to protect the public from unsanitary conditions arising from the operation of labor camps. This code prohibited any person from establishing or operating a labor camp without a permit from the local health officer and contained few regulations except those relating to the control of communicable diseases and the minimum distances which buildings of labor camps and more particularly sources of pollution may be maintained from lakes, ponds, streams, and sources of public water supply.

The urge to live outdoors and the rapid growth in automobile transportation enabling people to penetrate to the remotest parts of the country led to the establishment of numerous organized

summer camps for both children and adults and more recently the so-called "tourist" camps. Such organizations as the Boy Scouts, Girl Scouts, Y M C A, Y W C A, realizing the advantage from the standpoint of health, recreation, and character building of having children and young people live in the open under trained leadership for various lengths of time during the summer months established many summer camps throughout the country.

The inspection by this Department of some of the first summer camps established indicated the urgent need for the supervision over the sanitary conditions not only of labor camps but also of summer camps. Consequently, the Public Health Council on May 15, 1924, so amended Chapter V of the Sanitary Code as to apply to any camp or tract of land on which ten or more persons may camp, either free of charge or by the payment of a fee. In 1932 and again in 1935 the Sanitary Code relating to camps was so amended as to protect more adequately not only the public but more particularly the health of the campers.

In the last revision a camp was defined "to mean one or more temporary or permanent tents, buildings or structures, together with a tract of land pertaining thereto, established or maintained as living quarters for temporary occupancy by ten or more persons, including children, either free of charge or by the payment of a fee." This definition was designed to cover not only labor and summer camps but also most house-trailer camps and tourist camps having five or more cabins, assuming that each cabin could be occupied by two persons.

Our investigation of many of the summer camps established before the camp

code was enacted showed that there was gross ignorance on the part of the owners of even the most elementary principles of camp sanitation. Some camps were located on low, flat ground, adjacent to mosquito-breeding swamps where proper drainage could not be provided. Little thought seemed to have been given in many instances to selecting sites with suitable exposure and the existence of trees. Some were located where no trees were available for shade and others in woods so dense as to almost entirely shut out the sunlight and prevent the free movement of air.

The most serious defects, however, were those relating to water supplies in the camps. Wells from which the camp water supplies were obtained were found to be located often in close proximity to cesspools and privies and in some cases the overflow from cesspools and septic tanks was discharged into lakes, ponds, and other bodies of water close to intakes of camp water supplies or adjacent bathing beaches.

It was not surprising that such conditions should exist in camps established before the Sanitary Code was enacted for the guidance of camp owners. Most camps are operated and occupied by persons residing in municipalities provided with public water supplies and sewerage and sewage-disposal systems under competent control. The average citizen in cities pays little or no attention to such conveniences but takes them for granted.

As indicated above the selection of a site that will best meet the sanitary and health requirements is of prime importance. Careful consideration should be given to natural drainage, proper amount of shade, suitable exposure, sufficient area to provide desirable isolation, and adequate facilities for satisfactory water supply and sewage disposal.

To find camp sites that will meet all of the above desirable requirements is no easy matter and since the limited funds available, especially to charitable organizations, often prevent the securing of desirable sites, it becomes necessary to

make the most of such sites as it may be possible to secure. If, however, all of the regulations of the Sanitary Code are complied with not only in the construction but also in equipment, personnel, and operation, most camps can be so maintained as to protect the health, safety, and welfare of the campers.

The present code relating to camps contains forty regulations which cover in considerable detail such matters as cleanliness, sleeping quarters, ventilation and fly proofing, fire protection, protection of food supplies, dishwashing, kitchen and dining-room equipment, garbage disposal, camp personnel, special supervision of camps for children, medical and nursing care, isolation of cases of communicable diseases, water supply, sewage disposal, privies, swimming pools, bathing beaches, etc. Owing to the limited time available for the presentation of this comprehensive subject it will be possible to cover briefly only the more important requirements directly affecting the health of the campers, namely, water supply, sewage disposal, medical and nursing care, milk, and overcrowding in sleeping quarters.

A large part of the code is devoted to water supply, sewage, and waste disposal and rightly so, inasmuch as defects in these facilities and the use of raw milk have been the major causes of outbreaks of disease in camps. Unless the soil of a camp site is of a suitable porous nature the providing of a water supply of safe sanitary quality and adequate quantity and a satisfactory system of sewage disposal becomes a very difficult engineering problem. In fact it usually offers more difficulties than providing these facilities for a municipality. A city or village generally has sufficient funds to enable it to go a considerable distance to secure adequate supply of water and, if necessary, to install and operate adequate and efficient water-purification plants. Municipal sewer systems can be installed and the sewage conveyed to isolated points for treatment and disposal. In the case of camps, however, the funds available are limited and it is

generally necessary to secure a water supply and dispose of the sewage on relatively small camp sites

The safest source of water for a camp is the well or spring so located, constructed, and protected as to prevent wastes produced on the premises or from adjacent areas gaining access to the supply. Water supplies from surface sources such as streams, lakes, or ponds should be used only if an adequate supply of satisfactory sanitary quality cannot be obtained from ground water sources.

Surface supplies are almost invariably subject to willful or accidental pollution and cannot be considered safe for human consumption without effective filtration or chlorination, or both. Such purification or treatment processes are relatively costly to install and maintain, and to be dependable should be operated under trained and competent supervision which is rarely available at camps. Under no condition should a water supply for a camp be derived from a stream or other body of water into which untreated sewage or even treated sewage effluent is discharged, inasmuch as the interruption of the chlorination of such a supply is liable to cause an outbreak of water-borne disease.

Too much emphasis cannot be placed upon the safe disposal of sewage and human excreta. The Sanitary Code provides that "no privy shall be located less than 100 feet from any kitchen, dining room, or other place where food is prepared or served," and that "no leaching privies, cesspools, subsurface tile drains, sand filters, or other units of sewage treatment works which are not watertight should be located on the direct line of drainage to nor closer than 200 feet from wells, springs, ponds, reservoirs, or streams used as sources of water supply for a camp, etc."

Another section of the code provides, however, that a privy if not located on a direct line of drainage may be as close as 100 feet from the source of the camp water supply, but that a privy when located between 100 to 200 feet from such source of supply shall be so constructed

as to provide watertight receptacles for the storage of excreta.

Unless the soil of the camp is of a suitable porous nature and the site sufficiently large to provide for subsurface methods of sewage disposal, the installation of water closets and water-carriage systems of sewage disposal are discouraged and sanitary privies recommended. Water-carriage systems are costly to construct and require constant, intelligent operation in order to prevent the creation of objectionable conditions through overflows or the pollution of bodies of water which may be used as sources of supply or for bathing. If such systems are provided they should be designed and installed by experienced engineers.

Another very important regulation of the code is that relating to medical and nursing care. Regulation 33 of the code stipulates that "there shall be adequate medical and nursing supervision and care at or available to all camps." Some camp owners believed that they complied with this provision of the code if they employed a so-called "practical" nurse and an undergraduate medical student. In order to clarify this situation, the State Commissioner of Health last year appointed a committee consisting of District State Health Officers and members of the staff in the Central Office to study and report on this problem. The report of this committee, submitted on June 27, 1938, contains the following statement which is considered a reasonable interpretation of the minimum requirements necessary to comply with Regulation 33 of Chapter VII of the Sanitary Code.

1. At all camps there shall be

(a) A definite arrangement by the camp management with a licensed physician to be on call at all times for medical service and to supervise all first-aid and nursing service in the camp.

(b) Someone, either the camp manager or an employee, in the camp at all times, who is especially trained in first-aid service, such training to be that given by the American Red Cross in the "Advanced" course in first aid or its equivalent.

(c) Standing orders issued by the physician

to the person responsible for first-aid service to be followed in the absence of the physician

(d) A telephone in camp or available within 10 minutes travel time from camp

(e) A first-aid cabinet which shall be kept at all times fully equipped. A stretcher kept near the above cabinet. A first-aid bag which shall also be kept fully equipped and available for emergencies distant from the cabinet

(f) Definite arrangements to provide for any needed isolation facilities

2 At all camps operated to care for children not physically normal or at which the total number of persons, including campers, employees, and administrators, is at any time greater than 75, there shall be employed a resident registered nurse

3 At all camps at which the total number of persons, including campers, employees, and administrators is never at any time greater than 75, there shall be definite arrangements to provide for the employment of a registered nurse in camp whenever such employment shall be advised by the physician, and when he so advises a registered nurse shall be employed

If the total number of persons ordinarily approximates 75, the camp management should be encouraged and urged to meet the standards indicated in paragraph 2

At camps where there is a resident physician, requirements 1 (b), 1 (c), 1 (d), and 2 need not be required, but requirement 3 shall apply to all camps where there is a resident physician

The "definite arrangement" above referred to, shall be described in detail in writing by the camp manager and available for the guidance of the person in charge in the absence of the manager. "Definite arrangements" for personal service should preferably be written contracts and in detail as to authority and responsibility of both parties

Regulation 15 of the Sanitary Code relating to camps provides that "only milk and cream secured from a dealer holding a permit under Chapter III of the Sanitary Code shall be used at a camp." Milk permits are issued by local health officers to milk dealers only if the production and handling of the milk and cream meet the requirements of the code. It is invariably recommended

that only pasteurized milk, preferably in bottles, be used at camps. Large milk dealers are now able to deliver pasteurized milk to camps located in the remotest parts of the state so that there is no valid reason why most camps should not be provided with safe pasteurized milk. Raw milk, no matter how carefully it is produced and handled cannot be considered as safe as pasteurized milk. Of the large number of milkborne epidemics that have occurred in this state during the past twenty years no epidemic has been definitely traced to the use of properly pasteurized milk.

Another condition that should be avoided is the overcrowding in sleeping quarters. Regulation 12 requires that "A separate bed or other sleeping place shall be provided for each person cared for. Such beds or sleeping places shall be separated by a distance of at least two feet. Dormitories, rooms, or tents used for sleeping quarters shall have not less than thirty (30) square feet of floor area for each occupant and shall be properly ventilated." (This regulation does not apply to cabins of tourist camps.) In order to provide additional protection in camps occupied by children we recommend head to foot arrangement of sleeping cots whenever sleeping quarters are restricted. Conscientious carrying out of this regulation and head to foot sleeping arrangement should minimize the danger of spreading respiratory diseases among the campers.

As indicated above, the Sanitary Code places the supervision over the sanitary condition of camps almost entirely under the jurisdiction of the local health officers. It provides that "No corporation, association, or person shall establish or construct, or shall maintain any camp to be occupied by ten or more persons without a permit from the local health officer" and that application "for such permit shall be made in duplicate to the local health officer at least fifteen days before the opening of the camp on a form prescribed by the State Commissioner of Health." It also provides that "if the local health officer is satisfied after in

spection that the existing or proposed camp will not be a source of danger to the health of its occupants or to others and that it conforms to the requirements of the chapter (now known as Chapter VII of the Sanitary Code), he shall issue the necessary permit in writing." It provides further that the permit shall expire on December 31 following the day of issuance, and "that it may be revoked for cause either by the local health officer or by the State Commissioner of Health after a hearing."

The placing on the local health officers of the responsibility for the inspection of camps and the issuance of permits yearly has advantages as well as disadvantages. If the above provisions of the Sanitary Code could be complied with, the 3,000 camps in the state would be inspected at least once each year and steps could be taken to see that the provisions of the code would be met before the issuance of a permit to each particular camp. Many health officers, however, find it impossible to inspect all of the camps in their districts each year. Most of the camps are concentrated in summer resort regions such as the Catskills and Adirondacks and are occupied for only two or three months during the summer, which is the busiest time for the health officers, who naturally must give their private practice the right of way. Camp inspection is time consuming. It requires about a day to make a thorough original inspection of a large camp and perform the necessary office work in connection with the preparation of the report and the issuance of a permit. In some areas there are so many camps that it would require the entire time of the health officer during the summer months to make the necessary inspections and issue permits which, of course, could not be expected especially from part-time health officers. The result has been that a large number of permits have been issued to camps by health officers without inspection, and in many instances camps have been operated without permits.

As might be expected this lack of adequate supervision over camps has re-

sulted in the occurrence of a number of preventable outbreaks of disease. The majority of these outbreaks have been classed as gastroenteritis. Although the average number of cases per outbreak has been low, several have involved fifty or more cases. Fortunately the deaths have been very few.

In order to correct this condition and assist the health officers to more adequately supervise camps the Bureau of Camp Sanitation was established in the Division of Sanitation of the Department in 1935 with a well-qualified and experienced sanitary engineer in charge, and in 1937 it was possible through Social Security funds to employ 8 junior sanitary engineers for camp inspection. Before that time the inspection service provided by the engineers of the Department was limited to problems of an engineering nature when called upon for assistance by the health officers or camp authorities and to inspections by our field forces of organized children's camps, of which there are approximately 800 in this state.

The inspection by the junior engineers supplemented by our 19 district and assistant district engineers has resulted in marked improvements in the sanitary conditions of camps and has relieved health officers to some extent of the burden of camp inspections, although they continue in all cases to issue permits for the operation of camps as required by the Sanitary Code. Reports setting forth the results of the inspection by our engineers and making recommendations for needed improvements are sent to the camp authorities and to the local health officers for their information and guidance in issuing permits.

Funds for the employment of additional engineers for camp inspection were appropriated by the legislature [1939], thus making it possible for us to exercise much closer supervision over camps and prevent the occurrence of preventable outbreaks of disease due to overcrowding, unsafe water and milk supplies, and other unsatisfactory conditions. It is hoped that the Depart-

ment ultimately will be able to take over entirely the supervision of camps, including camp inspections and the issuance of permits and relieve local health officers of this responsibility. It is our aim to have all camps in this state so

constructed and operated that the occupants will have the same health and safety protection they receive at home so that parents may send their children to summer camps confident that they will return home healthy and happy.

WANTED—A DOCTOR

How does one go about the business of finding a good doctor? asks the *Detroit Medical News*. Does he go down the street with a lantern like Diogenes and look for an honest face or an appealing name? Or, as one wag puts it, does he simply spot the nearest office, inquire—"Doctor (Doc), next to yourself who is the best stomach, heart, kidney, and liver specialist hereabout?" and go there.

As a matter of fact, we are assured, possibly with a little more finesse, that is often the way it is done unless the physician first consulted has the wit to declare that by virtue of being the best he is also the next best in his field.

Mostly, however, the seeker of medical care does neither of these things. When the average citizen is concerned about his health he turns to his neighbor. The neighbor recommends a doctor toward whom, for a variety of reasons, he feels grateful. The doctor once upon a time may have accepted a sack of turnips for his fee when the "missus" was not doing very well or he may have arrived in the nick of time to push a peach pit down the gullet of junior when that worthy was turning all the colors of the rainbow and it seemed he surely must die. The point is, and let us make it clear, the grateful patient is the publicity agent par excellence of all doctors, and as his breed multiplies the physician's practice multiplies.

Who then is a good doctor? He must first of all be a safe doctor. The state laws are very stringent about the qualifications of the person who may be called to attend a sick horse, a cow, or a swine. He must be a doctor of veterinary medicine and be familiar with the anatomy, the physiology, and the pathology of the animal he is called to treat.

The person called to attend a human being who may be sick unto death need not be so qualified. Although doctors of medicine are rigidly examined by the state in these fundamentals, a horde of other persons who may be gloriously ignorant of the anatomy, physiology, or pathology of humankind are also licensed and given the privilege of treating the sick according to their own conceits.

Unless then you be a cow, a sheep or a pig, the seal of a great state upon the registration certificate of the person who has been asked to protect your life and your health is not a guarantee that he is a doctor of medicine or that he have even the elementary qualifications to perform the service you ask of him. The basic science law now effective in some states may in the future partly correct this abuse but today that is how it stands.

What are the qualities of a good M.D.? The wise and very human Thayer of Johns Hopkins held that the best physicians came from the middle thirds of their classes. The brilliant minds of the upper crust are too often detached from the common problems of life, their vision is too often telescopic so that they do not see what is beneath their very noses and they often have the air of never quite knowing what life is all about.

Einstein has said that the penalty of reading too much is to think too little so that the boys who know all the answers are often quite helpless when they are away from their books and are faced with new and trying situations. Sophistication is probably the greatest asset of the practicing physician, and he, who has freely associated with a wide variety of men, is already half a physician.

So when you go into a doctor's office and there is kitchen linoleum on the floor, oil cloth on the tables, mission furniture, "Dewey at Manila Bay" or "The Baptism of Pocahontas" adorning the walls, do not lift up your skirts. You are in the great working world, the world of the plain people. These are like the walls of home to the patient. The chances are that in 96 per cent of the cases no Osler, no Weir-Mitchell, no John B. Murphy could serve these plain people any better than the physician who is a resident there.

Let it be known that the requirements for entrance into the medical schools of America and for graduation as an M.D. are as rigid as at a West Point or Annapolis, that eight years are required for the attainment of the M.D. degree against the four years required to become an officer in the military service of the United States.

And finally there is the never ending program of postgraduate work that must be zealously pursued to keep abreast of the rapid advances in medical practice.

Let it be known that the modern doctor of medicine should therefore be a safe counselor wherever he be found. If when you consult him he takes a good history, asks you to remove your clothes, and carefully examines you however trifling your complaint, and if in addition he is well-met, can at all times be reached when you need him, you have found a good doctor.

Wanted, a doctor! Let it be known that your county medical society is at all times willing to give the names of neighborhood physicians. It will also, upon request, give the details of the training, the experience and the special interests of the doctor chosen.

THE USE OF SULFANILAMIDE IN THE TREATMENT OF HEMOLYTIC STREPTOCOCCIC EMPYEMA

LEON J. LEAHY, M.D., Buffalo, New York

(From the Department of Surgery, University of Buffalo School of Medicine)

ALTHOUGH the literature on the various aspects of sulfanilamide has been extensive, it is our opinion that its use in cases of hemolytic streptococcic empyema has not been settled. In reviewing the papers that have been written on this subject the impression was gained that there was considerable difference of opinion, not only as to the value of the drug in treating this condition but also as to the mode of administration. We wish to report a series of 7 consecutive cases in each of which sulfanilamide was administered. In some of our cases drainage was instituted in conjunction with the use of the drug, in others, with the exception of diagnostic aspiration, no type of drainage was employed.

Gay and Clarke, in experimental studies on rabbits, injected broth cultures of hemolytic streptococcus directly into the pleural cavity. These were of a fixed virulence and usually killed the animals in four to six days. The rabbits were fortified with sulfanilamide in relatively large amounts a few hours before the intrapleural infection with 1,000 to 2,000 M.L.D. The drug was continued for at least seven doses during the first two days, and an otherwise fatal empyema was aborted. The necessary dose was three daily subcutaneous injections, 20 cc each of a 2 per cent solution of the sulfanilamide crystals. These were dissolved in boiling water, then cooled to body temperature. This constituted a total of almost 3 Gm and effected complete protection against the streptococcus infection. It was noted by these authors that they were dealing with a preventative action and not with a true curative effect of the drug. In one rabbit in

which treatment was instituted twenty-four hours after the intrapleural infection, the animal survived for eleven days in contrast to the controls who uniformly died from four to six days. In a second rabbit, treatment was started forty-eight hours after the infection and death occurred on the fifth day similar to the controls. In further studies both controls and treated animals were sacrificed or died at various stages of the disease. In an untreated rabbit, killed in twelve hours, the increase of cocci was 6,500 times in twelve hours, whereas, in the treated animal this was only 10 times. This discrepancy became greater up to seventy-two hours, when the cultures were completely sterile in fully treated animals. The contrast between the amount of exudate was also very apparent, being markedly increased from twenty-four hours onward to the time of death in the control animals, and in only one of the treated animals was any appreciable amount of fluid present in the pleural cavity. In conclusion it is stated "Sulfanilamide prevents the evolution of an invariably fatal streptococcic empyema in rabbits when it was given repeatedly and in sufficient doses subcutaneously."

Tiling mentions the use of 5 cc of a 2½ per cent prontosil solution administered intrapleurally every two to three days combined with the removal of the empyema fluid (although it is not stated, I assume that this removal was accomplished by aspiration) and he reports cures in from seven to twenty-two days by this method. The number of cases is not noted in this article.

Klahn treated several cases of mixed tuberculous and streptococcic empyema with excellent results, by the intrapleural

use of 5 cc of a $2\frac{1}{2}$ per cent solution of prontosil. He also cites a case of spontaneous pneumothorax following a pneumolysis with a mixed hemolytic streptococcal and pneumococcal infection in the pleural cavity that responded readily to the intrapleural use of the drug with a fall of the temperature to normal in five days.

Further observations in favor of this method are made by Brown in a report of 2 cases of hemolytic streptococcal empyema. The first patient was given prontosil tablets by mouth with apparently no effect on the pleural exudate, however, the culture became sterile after the injection of 5 cc of prontosil solution into the pleural cavity. The strength of this is not noted. Repeated aspirations were sterile to culture and the pus, which he describes as very thick, became thinner, completely disappeared, and the lung re-expanded. In the second case a similar condition existed, namely, a collection of thick creamy pus in the pleural cavity, which yielded a pure culture of hemolytic streptococcus. Following the injection of 5 cc of prontosil solution into the pleural cavity the pus became thinner, sterile, and completely disappeared.

Nicholson states, in an article dealing with experimental work on rabbits, that the animals given prontosil solution into the pleural cavity in addition to a broth culture of hemolytic streptococcus died earlier than the animals receiving the culture alone, and that the treated animals yielded a higher percentage of positive cultures from the pleural cavity than the untreated. When prontosil solution was injected into the virgin pleural cavity, no gross damage to the tissues was noted, although a reduced local resistance was suspected in 1 case. It was his observation that the intramuscular injection of prontosil gave better results than its injection into the pleural cavity. He mentions that the only successes following intrapleural use of the drug occur in clinical reports, the number of cases rarely exceed 2 or 3. It is his observation that the cases reported

were those in which the first aspiration yielded thick pus. He feels that the injection of the drug may have little to do with the subsequent thinning of the exudate and the disappearance of the organism, because the dangerous stage of the disease is then passed, and suggests that the time when the drug is most indicated, is, of course, at the onset of the infection during the activity of the pneumonia in the formative stage of the empyema. It is his impression that the oral administration is more logical than the intramuscular or intravenous use, and that if the drug is introduced into the pleural cavity it should be combined with the oral administration. In summarizing, it is stated that the 15 untreated animals survived an average of seven and one-half days each, and culture of the pleural fluid was positive in 53 per cent. Seventeen animals that were treated with intrapleural prontosil survived an average of five and seven-tenths days with 70 per cent positive pleural cultures. Eight animals treated with intramuscular prontosil survived an average of seven and eight-tenths days with 37 per cent positive cultures from the pleural cavity. In conclusion, it was believed that the treated animals died earlier than the controls, and no sterility of the empyema was produced. In this series of experiments none of the animals was given the drug before the culture was introduced into the pleural cavity.

Dyke observes that in preparations examined by him it appeared safer to use the oral route rather than the parenteral injection.

Gmelin reports 2 cases of hemolytic streptococcal empyema both of which were treated by prontosil, orally. One was drained in addition to the administration of the drug, the other was not. In each instance there was a prompt recovery, one developing a normal temperature on the third day, the other on the sixth, both by lysis.

Bohrer reports a case of hemolytic streptococcal pneumonia in a 10 week-old child that ran a normal course and de-

veloped an empyema with absolutely no effect following the treatment with prontosil and prontylin. This child had, on a recent previous admission, been cured of erysipelas with the use of prontosil. He concludes his discussion with an expression of discouragement, because after several cases with spectacular results in the treatment of erysipelas, the drug was entirely negative in a group of 5 cases of hemolyzing streptococcic empyema.

Bahrdrdt reports good results with the use of prontosil in cases of streptococcic empyema. He does not report the number of cases or the method of administration.

Huber mentions 1 case of hemolytic streptococcic empyema in a boy 6 years of age who was aspirated frequently and given prontylin by mouth. Following therapy the temperature rapidly reached normal with a definite cure and disappearance of the purulent exudate.

Paffrath reports startling successes in a small series of cases of metastatic streptococcic empyema through the use of prontosil solution intramuscularly. The number of cases in this series is omitted.

Coryllos was enthusiastic about its use in a series of 5 cases of mixed infection tuberculous empyema in which hemolytic streptococcus was present. In his experience, the best results were obtained by the combined use of anti-streptococcic serum with prontosil and prontylin, and he notes that this type of treatment is far more effective than the treatment with either of the two alone. He further comments that the empyema fluid was sterilized in the course of four to five weeks.

Melnotte and Briquel report 7 cases of hemolytic streptococcic empyema that were treated with sulfanilamide, orally. They classify these into 5 that were treated early and 2 treated late. In the first 4 cases the hemolytic streptococcus present in the pleural fluid at the first tap disappeared in successive taps but the drug did not prevent the purulent transformation in Case 5, where pleurotomy was necessary. In each of these

cases the patient was a 21-year-old male. In Cases 6 and 7 treatment was started much later. In the former it was given on the forty-second day of an encysted purulent pleurisy which yielded hemolytic streptococcus on culture. Treatment was rubiazol, 8 tablets daily for eleven days, then 12 tablets daily for twelve days, the total was 136 tablets or 34 Gm. The patient was discharged after a slight relapse and apparently drainage was not performed. In the seventh case the treatment was started on the twenty-third day or nine days after a pleurotomy, which was done on the fourteenth day. In this instance the action of the drug was quite definite, the patient being cachectic with decubitus and was in an almost hopeless condition. There was sterile fluid in the right pleural cavity and thick pus in the left. On the fourteenth day following administration, the patient "vomited" streptococcus pus and the temperature slowly leveled off. Anti-streptococcic serum of Vincent was used in combination with rubiazol, and it was noted that the patient was improved at the time of publication. These authors feel that the use of the drug is warranted, even in cases that have had pleurotomy, and that it constitutes an important progress in the medical treatment of streptococcic purulent pleurisy. They feel that, if it does not cure these streptococcic empyemas, it at least improves conditions under which surgery may be done, or where suppuration is prolonged after surgery.

Gardner reports a case of hemolytic streptococcic paracarditis that went on to complete recovery following the oral use of the sulfanilamide without any type of drainage.

Basman and Perle report 2 cases, first of which was that of a 13-month-old boy with hemolytic streptococcic empyema following a lobar pneumonia eight weeks prior to admission. He had an open operation with a persistent sinus and recurring temperature about five weeks following removal of the tube. Physical signs and x-ray examination revealed that the left chest was filled with

fluid with displacement of the mediastinum, and a positive culture of hemolytic streptococcus was obtained from the sinus tract. Sulfanilamide was given by mouth. At the end of the first day the temperature returned to normal and remained there. Two days later a thoracotomy was performed and the child recovered. The second case was that of a 1-year-old boy presenting a hemolytic streptococcic empyema following a pneumonia of ten days duration. Closed drainage was performed and he was given the drug both intramuscularly and orally. The temperature gradually subsided for the following three days, but he again became septic. The drug was increased, but the child expired. A bronchopneumonia, bilateral empyema, and anterior mediastinitis were found.

Keefer mentions a fatal case of hemolytic streptococcic pneumonia with empyema and bacteremia that was treated by sulfanilamide, orally, and open drainage. Cultures from the empyemic cavity and blood stream became negative, but the patient died with a type XII pneumococcus pneumonia and bacteremia.

Hageman cites 5 cases of hemolytic streptococcic pneumonia, 3 of which had empyema when the treatment with sulfanilamide was instituted. He noted that in each instance, although a difficult therapeutic problem occurred through contraction of the chest and thickening of the pleura, the severity of the disease was modified. Two of the 3 cases required thoracotomy and all recovered.

Four interesting cases of infection within the chest that were treated with sulfanilamide are included in an article on the subject by Ballou and Goldbloom. First of these was that of an extremely sick child with multiple areas of streptococcic infection and draining sinuses following scarlet fever. There was one large deep abscess in the anterior thoracic region between the endothoracic fascia and the ribs with a question of mediastinal effusion. The child had several operations and numerous recognized forms of treatment, but in spite of

this, she continued her downward course. Prontylin was given and the response was dramatic. The temperature dropped to normal within twenty-four hours. The density in the chest cleared, there was a gain in weight, and the sinuses healed. In the second case there was a left lower lobar pneumonia with evidence pointing toward pus in the pleural cavity, although the presence of an unresolved pneumonia was suspected. On two occasions aspirations were productive of a clear type of fluid which on culture revealed hemolytic streptococcus. Although there were two fluid levels on the x-ray film with displacement of the mediastinum to the right, and a septic temperature, a definite pocket of pus could not be located on repeated needle punctures. The patient's condition became desperate and death was thought to be imminent. As a last resort treatment with prontosil intramuscularly was started, improvement was noted in twenty-four hours, and the patient was discharged from the hospital seventeen days later with a slightly elevated temperature. She was given prontylin and within two days her temperature dropped to normal. Case 3 is that of a boy, 6 years old, with signs of pneumonia with fluid at the left base. Aspiration yielded a blood-tinged, slightly purulent fluid from the left pleural cavity with no bacteriology noted. Prontylin, orally, was given in small doses, one tablet three times a day. After a prompt improvement he became acutely ill and prontosil intramuscularly was given, also two doses intravenously, with a fall in temperature and a gradual improvement in the physical signs. Subsequent thoracentesis revealed a dry tap. An x-ray film showed thickening of the pleura at the left base with presence of adhesions. The fourth case was one of a mixed infection empyema with open drainage, and the organisms recovered were staphylococcus and streptococcus. Prontylin was given in apparently small doses, a hemolytic streptococcic septicemia developed, and prontosil solution, in large doses, was injected intramuscularly. She also received prontylin,

orally, at this time, and 10 cc of the solution was instituted into the empyema cavity at each irrigation. The blood culture became negative, temperature dropped to normal, patient was discharged with a small residual empyema cavity. They observed that the discharge from the empyema was always scanty when prontylin or prontosil was given.

Lester, in a recent article, reports 4 cases of hemolytic streptococcic empyema in children, 3 of which were adequately treated with sulfanilamide, prontosil, or both, but in each instance surgery was necessary to effect a cure, and from the reports it does not appear as if the course of the empyema was altered in any way. In the fourth case the drug was used after surgery, and it was observed that this had the shortest drainage time in the series. The other favorable observations made by this author on the use of this drug in such cases was that all 4 recovered, although 3 of them were very sick and one was only 10 weeks old, also that the temperature before operation was lower than should ordinarily be expected. A reference accompanying this paper expressed the opinion that even in the light of added knowledge concerning sulfanilamide therapy, their impression about its application in empyema is not changed, and that the indications for surgery are just the same as they were before the drug was introduced.

The following cases are reported in detail, so that the progress of the disease under treatment might be noted.

The accompanying charts show the dosage of the drug, cultures of the pleural fluid, and temperature reactions.

Case Reports

Case 1—J H, male, aged 5½ years, Buffalo Children's Hospital

1/11/37 Forty-eight-hour attack of German measles with transient rash. History of other members of the family with similar condition. Associated cold kept him in bed for one week.

1/19/37 Developed a high fever with anorexia and a severe cough.

1/21/37 Respirations became labored.

FIG 1

1/24/37 Admitted to the hospital. Temperature 102.5 F, pulse 140, respirations 40. Child appeared acutely ill with labored respirations but no apparent cyanosis. Anterior cervical nodes enlarged, eardrums slightly injected, pharynx and tonsils reddened, signs of fluid in the right chest from the axilla to base. Bronchial breathing over right apex, abdomen slightly distended, spleen palpable. Hemoglobin 106, rbc 5,200,000, wbc 38,250, polymorphonuclears 84 per cent. X-ray examination revealed fluid in the right pleural cavity. Aspiration yielded 270 cc of yellow cloudy fluid which yielded a pure growth of streptococcus hemolyticus on culture.

1/26/37 Administration of prontosil, intramuscularly.

1/27/37 On thoracentesis 85 cc of yellow cloudy fluid, which was positive on culture for hemolytic streptococcus, was withdrawn.

1/29/37 Chest fluid still gave a positive culture for streptococcus hemolyticus. Blood culture negative. Temperature remained elevated.

2/1/37 Culture of chest fluid negative.

2/3/37 Culture of chest fluid again negative.

2/4/37 Examination of the chest revealed dullness throughout the right side with suppressed breath sounds. X-ray showed that the opaque shadow was less in density and smaller in area than on previous examination.

2/11/37 Temperature has been septic in type for the past three days reaching as high as 104 F. No fluid was obtained on aspiration of the chest.

2/14/37 Blood culture negative. Temperature reached normal and remained so until discharge. Pulse varied between 120 and 140 dur-

fluid with displacement of the mediastinum, and a positive culture of hemolytic streptococcus was obtained from the sinus tract. Sulfanilamide was given by mouth. At the end of the first day the temperature returned to normal and remained there. Two days later a thoracotomy was performed and the child recovered. The second case was that of a 1-year-old boy presenting a hemolytic streptococcic empyema following a pneumonia of ten days duration. Closed drainage was performed and he was given the drug both intramuscularly and orally. The temperature gradually subsided for the following three days, but he again became septic. The drug was increased, but the child expired. A bronchopneumonia, bilateral empyema, and anterior mediastinitis were found.

Keefer mentions a fatal case of hemolytic streptococcic pneumonia with empyema and bacteremia that was treated by sulfanilamide, orally, and open drainage. Cultures from the empyemic cavity and blood stream became negative, but the patient died with a type XII pneumococcus pneumonia and bacteremia.

Hageman cites 5 cases of hemolytic streptococcic pneumonia, 3 of which had empyema when the treatment with sulfanilamide was instituted. He noted that in each instance, although a difficult therapeutic problem occurred through contraction of the chest and thickening of the pleura, the severity of the disease was modified. After a prompt improvement he became acutely ill and prontosil intramuscularly was given, also two doses intravenously, with a fall in temperature and a gradual improvement in the physical signs. Subsequent thoracentesis revealed a dry tap. An x-ray film showed thickening of the pleura at the left base with presence of adhesions. The fourth case was one of a mixed infection empyema with open drainage, and the organisms recovered were staphylococcus and streptococcus. Prontylin was given in apparently small doses, a hemolytic streptococcic septicemia developed, and prontosil solution, in large doses, was injected intramuscularly. She also received prontylin,

FIG 4

solution, intramuscularly, administered. Temperature had risen to 103 F on the two previous afternoons. X-ray examination revealed only a small amount of fluid present.

2/25/37 Seventy-five cc of thick pus removed on aspiration in the fifth interspace, posteriorly. This showed gram-positive cocci in short chains on smear and streptococcus hemolyticus on culture.

2/26/37 Open drainage was instituted by removal of a portion of the eighth rib in the posterior axillary line on the left side under local anesthesia. An empty empyemic cavity was opened into, it contained no fluid or pus, only a small amount of fibrin being present. Histologically, this fibrin showed a hemorrhagic exudate with a fair number of leukocytes with no organisms seen and on culture only a few colonies of streptococcus hemolyticus.

2/28/37 Temperature normal, remained so.

3/3/37 Large drainage tube removed and Dakin's tube left for irrigations. The child developed an impetigo lesion on the face and was again put on prontosil therapy. This rapidly cleared up. Culture of this lesion showed the presence of streptococcus hemolyticus.

4/2/37 Repeated x-ray films of the chest showed a progressive improvement.

4/8/37 Child discharged apparently cured.

8/18/37 Fracture of the both bones of the right forearm, healed with no complications.

2/21/38 Admitted for tonsils and adenoids. Uneventful convalescence.

6/4/38 X-ray of the chest shows the lungs entirely clear with no pleural thickening.

Comment

The above is a case of hemolytic streptococcal empyema apparently of long standing. The child was operated upon because of the large amount of fibrin in the exudate and septic temperature,

FIG 5

however, there was very little, if any, drainage and the cavity was free from fluid at the time of operation. The tube was withdrawn at the end of four days, and the lung completely re-expanded in spite of the pleural thickening which was present. I am not convinced that the operation influenced the convalescence particularly and, possibly, was unnecessary.

Case 3—R.C., female, aged 6 years, 10 months, Buffalo Children's Hospital.

2/23/37 Illness with high fever and skin eruption which apparently was measles. On the following day child had fever, weakness, chills, and dyspnea. Temperature was higher at night than during the day.

3/3/37 Both eardrums ruptured spontaneously.

3/8/37 Labored and noisy respirations were noticed.

3/9/37 Admitted to the hospital, temperature 105.2 F, pulse 132, respirations 40. Child appeared critically ill with labored respirations and slight cyanosis. Cervical nodes moderately enlarged, bilateral otitis media, limited expansion of the left chest with scattered coarse and fine rales throughout both sides, dullness to percussion, and distant breath sounds in the left interscapular region, early clubbing of fingers. Urinalysis 4 plus albumin, 1 plus sugar, and many white cells, leukocytes 24,000, segs 6, stabs 20, lymphs 1, monosaccharides 4, tuberculin and Kahn tests negative. X-ray examination of the chest showed an opacity in the left base with no displacement of the mediastinum. Aspiration of the left chest revealed

FIG 2, CASE 1 Fluid in the right pleural cavity before treatment was instituted

ing his stay in the hospital. Respirations ranged around 40 for the first week, 30 the second week, and 24 for the third week. Marked clinical improvement was progressively noted with a gradual clearing of the right chest, except for a slight dullness on percussion note on the right side, which was noted at the time of his discharge on March 9.

9/3/37 Child was admitted for drainage of an inguinal abscess. Culture of the pus showed staphylococcus aureus nonhemolyticus, this promptly healed.

6/24/38 Check-up x-ray examination of the chest showed the right chest to be perfectly clear with no pleural thickening present.

Comment

The above is a proved case of hemolytic streptococcal empyema which seems to have been cured by chemotherapy. The aspirations done were largely of a diagnostic nature, only a small amount of fluid being withdrawn for culture on most occasions.

At the time I first saw this patient, culture of the chest fluid was negative, the child having been treated on the pediatric service. At the time of the secondary rise in temperature I planned to institute surgical drainage, but no

fluid could be obtained on aspiration and the marked clinical improvement, which promptly followed, precluded the necessity for surgery. The convalescence seems to be complete.

FIG 3, CASE 1 Lung almost completely expanded two weeks later, no fluid obtained on aspiration

Case 2—M M, female, aged 3 years 4 months, Buffalo Children's Hospital.

10/1/36 Child had a severe cough lasting for five weeks, which the mother assumed to be whooping cough, following this she never fully regained her health, being tired, weak, and having lost weight, with poor appetite and a slight persistent nonproductive cough.

2/19/37 Admission to the hospital because of the above symptoms. Temperature 99.6 F, pulse 130, respirations 28. Child did not appear acutely ill. Pharynx slightly reddened and anterior cervical nodes palpable. Chest examination revealed limited motion on the left side with dullness and absent breath sounds over the entire left chest anteriorly and posteriorly. Apex beat slightly displaced to the right. Hemoglobin 90 per cent, wbc 16,000, polymorphonuclears 84 per cent. Tuberculin and Kahn tests negative. X-ray examination revealed an opacity in the lower two-thirds of the left chest without any mediastinal displacement.

2/20/37 Thirty cc of thick yellow pus removed from the left side. Positive on culture for hemolytic streptococcus.

2/24/37 Prontosil orally and protargin

FIG 4

solution intramuscularly, administered. Temperature had risen to 103 F on the two previous afternoons. X-ray examination revealed only a small amount of fluid present.

2/25/37 Seventy-five cc of thick pus removed on aspiration in the fifth interspace posteriorly. This showed gram-positive cocci in short chains on smear and streptococcus hemolyticus on culture.

2/26/37 Open drainage was instituted by removal of a portion of the eighth rib in the posterior axillary line on the left side under local anesthesia. An empty empyemic cavity was opened into, it contained no fluid or pus, only a small amount of fibrin being present. Histologically, this fibrin showed a hemorrhagic exudate with a fair number of leukocytes with no organisms seen and on culture only a few colonies of streptococcus hemolyticus.

2/28/37 Temperature normal, remained so.

3/3/37 Large drainage tube removed and Dakin's tube left for irrigations. The child developed an impetigo lesion on the face and was again put on prontosil therapy. This rapidly cleared up. Culture of this lesion showed the presence of streptococcus hemolyticus.

4/2/37 Repeated x-ray films of the chest showed a progressive improvement.

4/8/37 Child discharged apparently cured.

8/18/37 Fracture of the both bones of the right forearm healed with no complications.

2/21/38 Admitted for tonsils and adenoids. Uneventful convalescence.

6/4/38 X-ray of the chest shows the lungs entirely clear with no pleural thickening.

Comment

The above is a case of hemolytic streptococcal empyema apparently of long standing. The child was operated upon because of the large amount of fibrin in the exudate and septic temperature,

FIG 5

however, there was very little, if any, drainage and the cavity was free from fluid at the time of operation. The tube was withdrawn at the end of four days, and the lung completely re-expanded in spite of the pleural thickening which was present. Urinalysis 4 plus albumin, 1 plus sugar, and many white cells, leukocytes 24,000, segs. 6, stabs 29, lymphs 1, monosaccharides 4, tuberculin and Kahn tests negative. X-ray examination of the chest showed an opacity in the left base with no displacement of the mediastinum. Aspiration of the left chest revealed

FIG 2, CASE 1 Fluid in the right pleural cavity before treatment was instituted

ing his stay in the hospital. Respirations ranged around 40 for the first week, 30 the second week, and 24 for the third week. Marked clinical improvement was progressively noted with a gradual clearing of the right chest, except for a slight dullness on percussion note on the right side, which was noted at the time of his discharge on March 9.

9/3/37 Child was admitted for drainage of an inguinal abscess. Culture of the pus showed staphylococcus aureus nonhemolyticus; this promptly healed.

6/24/38 Check-up x-ray examination of the chest showed the right chest to be perfectly clear with no pleural thickening present.

Comment

The above is a proved case of hemolytic streptococcal empyema which seems to have been cured by chemotherapy. The aspirations done were largely of a diagnostic nature, only a small amount of fluid being withdrawn for culture on most occasions.

At the time I first saw this patient, culture of the chest fluid was negative, the child having been treated on the pediatric service. At the time of the secondary rise in temperature I planned to institute surgical drainage, but no

fluid could be obtained on aspiration and the marked clinical improvement, which promptly followed, precluded the necessity for surgery. The convalescence seems to be complete.

FIG 3, CASE 1 Lung almost completely expanded two weeks later, no fluid obtained on aspiration

Case 2—M. M., female, aged 3 years 4 months, Buffalo Children's Hospital.

10/1/36 Child had a severe cough lasting for five weeks, which the mother assumed to be whooping cough, following this she never fully regained her health, being tired, weak, and having lost weight, with poor appetite and a slight persistent nonproductive cough.

2/19/37 Admission to the hospital because of the above symptoms. Temperature 99.6 F, pulse 130, respirations 28. Child did not appear acutely ill. Pharynx slightly reddened and anterior cervical nodes palpable. Chest examination revealed limited motion on the left side with dullness and absent breath sounds over the entire left chest anteriorly and posteriorly. Apex beat slightly displaced to the right. Hemoglobin 90 per cent, white 16,000, polymorphonuclears 84 per cent. Tuberculin and Kahn tests negative. X-ray examination revealed an opacity in the lower two-thirds of the left chest without any mediastinal displacement.

2/20/37 Thirty cc of thick yellow pus removed from the left side. Positive on culture for hemolytic streptococcus.

2/24/37 Prontosil orally, and penicillin

Chart of CP

FIG 8

opacity over the entire right side with some displacement of the heart. A thoracentesis was done on the right side and 225 cc of thin yellowish fluid was removed. Smear showed gram-positive cocci in chains which on culture proved to be streptococcus hemolyticus.

4/6/37 Prontylin therapy was begun and child was transfused.

4/8/37 X-ray examination showed an area of pneumothorax in the lateral right chest wall with fluid level at the base, the lung being somewhat compressed, and heart displaced to the left.

4/9/37 Aspiration revealed 50 cc of straw-colored fluid with some air. Culture positive for hemolytic streptococcus. A spinal puncture was done which revealed five cells, negative globulin and negative copper reduction.

4/12/37 Diagnostic aspiration yielded fluid which was positive on culture for hemolytic streptococcus. Transfused.

4/14/37 Transfused.

4/18/37 Diagnostic aspiration revealed fluid which was positive on culture for hemolytic streptococcus only after seventy-two hours.

4/20/37 X-ray examination showed much better lung expansion and no evidence of fluid.

4/24/37 Diagnostic aspiration revealed fluid which was sterile on culture.

4/29/37 X-ray examination showed continued improvement with gradual re-expansion of the lung.

5/5/37 Discharged.

6/21/37 X-ray of the chest showed both lungs clear with no pleural thickening.

Comment

I feel that this case of hemolytic strep-

FIG 9 CASE 4 Opacity throughout the entire right chest with mediastinal displacement

tococcic empyema with a synpneumonic area in an infant, having gone on to complete recovery, is quite conclusive. There was a large amount of infected fluid present in the pleural cavity, which subsequently became sterile with complete absorption, re-expansion of the lung, and no pleural thickening. The aspirations were largely only of a diagnostic nature.

FIG 10, CASE 4 Lung re-expanded no fluid or apparent pleural thickening

Case 5 — M. B., female, aged 5 years, 5 months, Buffalo Children's Hospital

FIG 6, CASE 3 Accumulation of fluid at the left base, positive on culture for streptococcus hemolyticus

thin fluid which yielded a pure culture of hemolytic streptococcus. Child was placed in an oxygen tent, fluid balance maintained, prontosil therapy instituted.

3/16/37 Child out of oxygen much improved, fluid markedly lessened in amount. Five cc of straw-colored fluid removed from the left chest which was sterile on culture.

3/17/37 X-ray examination revealed a longitudinal opacity along the lateral chest wall presumably due to encapsulated fluid and pleural thickening.

3/22/37 Chest tap revealed fluid which was sterile on culture.

3/23/37 Parents signed release for discharge of this child against our advice and without our consent. Temperature, pulse, and respirations were normal.

4/19/37 Child was admitted to the Emergency Hospital with signs of empyema in left chest, fluid revealed streptococcus, staphylococcus, and pneumococcus.

4/21/37 Open drainage performed on the left side.

5/2/37 Drainage tube removed.

5/10/37 Child discharged as cured. She was practically afebrile during her stay in the hospital.

Comment

The response in this case was so prompt it is hard to understand how there was a recurrence of the empyema on the left side and also, how infection became

mixed. I feel that perhaps therapy was not intensive enough and was discontinued too early, and that it is more than likely that the pleural infection could have been controlled without surgery under different handling.

FIG 7, CASE 3 At the time of discharge showing encapsulated pocket of fluid which was negative on culture.

Case 4—C P, female, aged 9 months, Buffalo Children's Hospital.

At the age of two months treated for congenital lues with beginning optic atrophy.

At the age of 5 months bronchopneumonia on the right side, convalescence complete in twelve days.

At the age of 7 months admitted for diarrhea and discharged as cured in four days.

4/2/37 Child was taken ill with severe attack of vomiting and coughing. The mother noticed the child's breathing was labored and difficult, and a physician diagnosed the case as bronchitis.

4/5/37 Child admitted to the hospital, temperature 103 F, pulse 150, respirations 60. She appeared acutely ill with moderate cyanosis of the lips and fingernails. Examination of the chest revealed dullness to flatness throughout the whole right side with distant breath sounds over the lower portion and tubular breathing with a few fine rales in the apical region. There were occasional areas of bronchial breathing on the left side. The heart was slightly displaced to the left and abdomen distended. Hemoglobin 35 per cent, wbc 16,200, polymorphonuclears 85, lymphs 12, mononuclears 1, eosinophils 1, urinalysis negative, Kahn negative. X-ray examination of the chest showed an

Chart of CP

FIG 8

opacity over the entire right side with some displacement of the heart. A thoracentesis was done on the right side and 225 cc of thin yellowish fluid was removed. Smear showed gram-positive cocci in chains which on culture proved to be streptococcus hemolyticus.

4/6/37 Prontylin therapy was begun and child was transfused.

4/8/37 X-ray examination showed an area of pneumothorax in the lateral right chest wall with fluid level at the base, the lung being somewhat compressed and heart displaced to the left.

4/9/37 Aspiration revealed 50 cc of straw-colored fluid with some air. Culture positive for hemolytic streptococcus. A spinal puncture was done which revealed five cells, negative globulin and negative copper reduction.

4/12/37 Diagnostic aspiration yielded fluid which was positive on culture for hemolytic streptococcus. Transfused.

4/14/37 Transfused.

4/18/37 Diagnostic aspiration revealed fluid which was positive on culture for hemolytic streptococcus only after seventy-two hours.

4/20/37 X-ray examination showed much better lung expansion and no evidence of fluid.

4/24/37 Diagnostic aspiration revealed fluid which was sterile on culture.

4/29/37 X-ray examination showed continued improvement with gradual re-expansion of the lung.

5/5/37 Discharged.

6/21/37 X-ray of the chest showed both lungs clear with no pleural thickening.

The aspirations were largely only of a diagnostic nature.

FIG 10 CASE 4 Lung re-expanded, no fluid or apparent pleural thickening

Case 5—M B, female, aged 5 years, 5 months
Buffalo Children's Hospital

Chart of M B

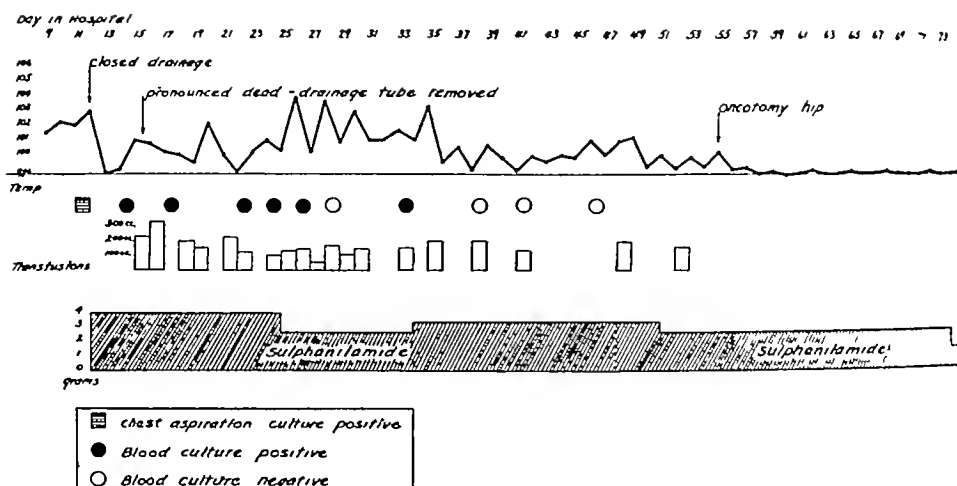

FIG 11

4/24/37 Child began to have abdominal pain and vomiting associated with a severe cough. Symptoms persisted for six days following which improvement was noted.

5/1/37 Admitted to the hospital. Sent in with the diagnosis of acute appendicitis. Temperature 105 F, pulse 140, respirations 30. Child appeared acutely ill, respirations were labored and noisy, face was flushed but no cyanosis, pharynx reddened. Impaired resonance over the right base, increased vocal and tactile fremitus throughout this area, scattered rales in the left chest, abdomen essentially negative. Urinalysis and tuberculin test negative. Hemoglobin 90 per cent, r b c 4,800,000, w b c 15,200, polymorphonuclears 86%, eosinophils 1%. X-ray examination revealed bronchopneumonia in both lungs. Child ran a temperature ranging for most of the time between 102 F and 103 F until May 9, 1937, when it reached normal.

5/8/37 Throat culture yielded staphylococcus aureus nonhemolyticus.

5/10/37 Temperature again elevated to 102 F and x ray film revealed fluid in the left chest.

5/11/37 Aspiration of chest revealed a rather thick fluid which on culture showed streptococcus hemolyticus. Sulfanilamide was given by mouth.

5/12/37 A report of staphylococcus aureus, which was intended for the throat, was erroneously made as having come from the pleural cavity, and as the fluid contained considerable fibrin a small portion of the eighth rib was resected under local anesthesia and drainage tube inserted into the pleural cavity. The wound was

closed tightly about the tube and closed drainage maintained.

5/13/37 Blood culture revealed streptococcus hemolyticus.

5/14/37 Marked interstitial emphysema which gradually developed from the time of operation, now extended over the entire body. Sutures were loosened about the tube and the drainage converted to open. Temperature reached normal.

5/15/37 The child ceased breathing from four to five minutes, was pulseless, had dilated pupils, and was thought to have expired. Drainage tube was removed and considerable sloughing had taken place about the operative wound leaving an opening through which the diaphragm and lower lobe were visible. Child began to breathe, her pulse became perceptible, temperature rose to 103 F. The tube was not replaced because there appeared to be adequate drainage and no tendency for the opening to close. There was no paradoxical breathing.

5/27/37 X-ray examination showed that the left lung was re-expanding. There was no filtration in the left upper chest, but no fluid or pleural thickening was visible. Marked interstitial emphysema.

6/4/37 Smear from the pleural cavity showed a streptococcus hemolyticus and staphylococcus albus. Patient was given a total of nineteen transfusions of citrated blood varying in amounts from 50 to 330 cc. Regular blood counts and urinalyses were done showing varying degrees of anemia and nothing remarkable in the urine.

6/7/37 Blood culture was sterile for the first time.

FIG 12, CASE 5 Large accumulation of fluid in the left chest.

6/8/37 Child resumed a septic type of temperature reaching 104 F daily, pulse varied between 140 and 160 Dakin's tube was inserted in the wound for irrigations

6/10/37, 6/12/37, 6/14/37 Sterile blood cultures Temperature reached a lower level rising only to a peak of 101 F

6/25/37 X-ray examination of the chest showed the left lung re-expanded with no evidence of pleural thickening or fluid The interstitial emphysema had disappeared and there was an upward dislocation of the right hip with a soft tissue swelling about the left hip The abscess about the left hip was drained and the culture of the pus revealed streptococcus hemolyticus The right hip was placed in traction Following drainage of the abscess about the hip the temperature dropped and never again rose above 100 F rectally, being normal most of the time and remaining so after August 1

7/16/37 X-ray examination of the chest from two planes showed good expansion of the left lung There was some pleural thickening and no fluid present Wound in left chest closed so that only a small sinus was present

7/24/37 She developed pain and photophobia in the left eye. Ten days later there appeared an intense circumcorneal injection with cloudiness of the cornea. This was diagnosed as a phlyctenular keratitis During her convalescence in the hospital she was placed on an intense vitamin therapy

FIG 13, CASE 5 Two weeks postoperative re-expansion of the lung, pleural thickening, interstitial emphysema

8/18/37 She was discharged to the outpatient department

8/20/37 Wound was entirely healed, following this she was seen for several months in the outpatient department with progressive improvement of both the eye and the hip

9/24/37 Patient was allowed off crutches at which time hips had a normal appearance.

6/27/38 X-ray examination of the chest showed it to be perfectly clear with no pleural thickening

FIG 14, CASE 5 Showing disappearance of the interstitial emphysema, lung almost completely re-expanded, slight pleural thickening

Comment

This child was desperately ill and had several rather serious complications. I do feel that she would not have survived her illness without the help of sulfanilamide. The drainage tube was left in the chest for only three days and in spite of this, the pleural cavity became eventually sterilized and the lung went on to complete re-expansion. Child's condition became much more grave following the operation, and I feel very strongly that a more conservative type of treatment might have been better.

FIG 15

Case 6—J F, male, aged 7 years, Buffalo Children's Hospital

1/4/38 Admitted to the hospital. Temperature 104½ F, pulse 160, respirations 40. Child was taken ill on the morning of admission with pain in the epigastrium, which later shifted to the right lower quadrant with vomiting. He also had a cough, chills, and felt feverish. He appeared acutely ill and examination of the chest revealed distant breath sounds and dullness over the right base, posteriorly. Urinalysis, Katin, and tuberculin tests all negative. X-ray examination showed a small area of pneumonia at the base of the right lung.

1/7/38 After three days of bed rest, sedatives, fluids, and continuous oxygen, child ran a temperature of 104 F, with practically no remission since admission. Pulse 104, respirations between 40 and 50. Physical examination revealed flatness with absent breath sounds throughout the right lower chest. A thoracentesis was done and 140 cc. of yellowish fluid withdrawn, the

FIG 16

culture of which revealed streptococcus hemolyticus. X-ray examination on this date showed the area of pneumonia in the lower lobe of the right lung had increased in size. The heart and trachea were displaced to the left. Right diaphragm was obscured.

1/10/38 Aspirations were performed almost daily and all of the fluid that could be obtained was withdrawn, each specimen revealed a positive culture for streptococcus hemolyticus. Five blood transfusions were performed. Treatment with sulfanilamide by mouth.

1/13/38 Sulfanilamide estimation in the blood was 4.6 mg per cent, in chest fluid 2.0 mg.

1/14/38 Temperature gradually reached normal, pulse 90, respirations 30. Blood count revealed hemoglobin 146 per cent, rbc 7,620,000, wbc 29,300, polymorphonuclears 40, lymphs 6. His temperature had started a gradual upward climb and reached 102 F on January 17. Blood culture sterile.

1/15/38 Temperature began to rise. X-ray examination showed an increase in the amount of fluid, and the displacement of the heart and trachea to the left. Child was markedly cyanotic and dyspneic and although his condition was desperate, closed drainage was performed. His temperature continued to rise and he became markedly jaundiced and expired January 18, 1938. Permission for autopsy was refused.

Comment

This represents our only fatal case, it was an extremely progressive type of infection even though closed drainage was instituted. There are several factors which should be considered. First, a tube could have been introduced into the chest earlier, second, the dose of the drug could have been larger, third, the transfusions could have been fewer with a more careful check of the blood count.

FIG 17, CASE 7 Congestion of the lower right chest with accumulation of fluid in the pleural cavity

There was no time during the course of this boy's illness when he presented even a fair risk for any type of drainage but I feel that as long as it was done eventually, it could have been performed earlier but we hesitated because the exudate was watery in consistency

Case 7—F M, female, aged 20 Buffalo General Hospital

1/25/38 She contracted a cold but continued her school work for a week in spite of constant headache, malaise, and a dry, hacking cough accompanied by blood-streaked sputum

2/1/38 Complained of severe attack of pain in the right chest and right side of her back with chilly sensations She continued to raise rusty sputum and called a physician

2/3/38 Admitted by ambulance Examination revealed a rather poorly developed, undernourished, acutely ill adult white female Temperature 105 F, pulse 130, respirations 30 There was no cyanosis nor marked dyspnea Marked injection of the nasopharynx, tongue dry and coated, anterior cervical nodes were palpable Examination of the chest revealed impaired resonance of the right side posteriorly diminished breath sounds and high-pitched prolonged inspiration. There were fine rales present in the aforementioned area Left chest was negative as was the remainder of the physical examination Hemoglobin 88 per cent, rbc 3 760 000 wbc 19,850, polymorphonuclears 88 many bands and juveniles Because of a

family history of tuberculosis, she had a biannual chest x-ray in the outpatient department Blood culture taken on February 3, 1938, reported sterile after five days Portable radiographic examination of the chest revealed congestion in the right lung, especially in the lower two-thirds, which was considered a pneumonic process

FIG 18, CASE 7 Complete re-expansion of the lung some pleural thickening present infiltration about the hilus

2/4/38 Sputum examination revealed presence of pneumococcus type VI and streptococcus hemolyticus

2/5/38 Sulfanilamide therapy was begun

2/6/38 Temperature rose to 106 F, pulse 140, respirations 30 and there was some cyanosis She was put in an oxygen tent and 50 per cent glucose was given intravenously

2/8/38 A Keidel tube filled with yellowish cloudy fluid withdrawn from the right pleural cavity This was negative on direct smear but on culture yielded a pure growth of hemolytic streptococcus

2/10/38 Patient's condition continued to be desperate, there was found to be consolidation in the upper part of the lower lobe with fluid at the base and displacement of the heart to the left Radiographic examination of the chest showed a marked density of the entire right chest displacing the trachea to the left

2/14/38 Sulfanilamide determination in the blood 27 mg per cent, in the chest fluid 30 mg Seven hundred and twenty cc of clear

yellowish fluid removed from the right chest which was sterile on culture

2/17/38 There were still signs of consolidation, but the voice sounds were coming through more clearly and, anteriorly, the resonance was markedly improved. Temperature had gradually fallen to normal, although the pulse remained at 120. Patient was allowed out of oxygen for part of the day and seemed quite comfortable.

2/19/38 Sulfanilamide determination in the blood 13 mg

2/21/38 No fluid was obtained on aspiration in several different areas

2/26/38 Patient had had a temperature of 101 F and 102 F on two occasions, but there was a phlebitis from the intravenous administration. Chest was aspirated through a large caliber needle, nothing was obtained, except a small amount of fibrin. Direct smear showed scattered leukocytes, but no organisms. This was sterile on culture. X-ray examination of the chest still revealed an opacity at the periphery of the right chest extending from the first rib down to the diaphragm. There was no fluid level seen and this area had diminished to one-half of its previous size.

3/1/38 Patient's general condition was reported as excellent. Temperature showed only an elevation of one-half degree daily for the past week, however, there was an area of dullness roughly conforming to the right interlobar fissure.

3/19/38 Patient had been sitting up in bed and had felt very comfortable, except for an occasional pain in the right chest. Pulse had dropped to 80, respirations were normal, temperature showed a daily rise of one-half degree. Expansion of the right chest was limited somewhat and the percussion note slightly impaired over the base from the ninth interspace down. The breathing sounds were also slightly diminished in this area.

3/24/38 Dullness and egophony in the region of the fissure, posteriorly. Leukocytes 6,800. X-ray still revealed a congestion in the region of the middle lobe.

4/25/38 Patient's condition showed gradual improvement, although the x-ray film still showed a density in the region of the middle lobe with no change in the physical findings. Temperature had been normal for the last week.

5/9/38 Improvement continued, temperature remained normal, physical findings were negative, x-ray film showed a diminution in the size of the density in the region of the interlobar fissure.

5/17/38 Patient discharged, having gained

fifteen pounds in weight, although the x-ray film still showed a density in the region of the interlobar fissure.

8/26/38 Admitted to the J N Adam Memorial Hospital with sputum positive for tubercle bacilli, and a lesion in the right chest.

Comment

This patient was extremely ill and a very poor candidate for any type of drainage. Although her empyema was very definite, and her treatment not particularly intensive, she made a complete recovery from her empyema with the drug by mouth alone.

In view of the subsequent developments, it is fortunate that drainage was not done, because there might easily have been a persistent sinus with a chronic empyema, as a result of her tuberculous infection.

Discussion

Cases 1, 4, and 7 represent proved cases of hemolytic streptococcal empyema. In all 3 there appeared to be an active pneumonic process at the time the empyema was diagnosed and treatment with the drug was instituted. These all recovered without drainage. Case 2 was particularly instructive to me because on entering the pleural space, I found an empyemic cavity present which contained no fluid pus, but merely some plastic exudate in small amounts, which yielded a growth on culture medium very slowly. Following removal of the tube after four days and continuance of the drug, the convalescence continued rapidly. It was our impression that we had instituted drainage in a late case that was proceeding toward convalescence. In Case 5 also the drainage tube was removed after three days but there was no recurrence of the empyema. Case 6 apparently represents an instance in which the drug had no influence over the infection as does our recent case reported in brief.

Whether or not this series of 7 cases above reported is large enough to draw conclusions is open to considerable question. It is difficult to accumulate a very

much larger group in the short time that has elapsed since the use of this drug was instituted. These represent all the instances that occurred on two fairly active services over a period covering two years and four months. It happens that the majority of these cases occurred in the year 1937 when we were just beginning to use the drug in streptococcal pneumonias. There was only 1 case in the Buffalo Children's Hospital during 1938, which fact seemed quite unusual, and during this period the drug was used much more routinely in the children having what was thought to be streptococcal pneumonia. Roughly speaking, the streptococcal pneumonia admissions in 1938 were twice as many as in 1937. In spite of this fact the percentage of empyema in the 1937 cases was five times as great as in 1938. Up to date there has been only 1 case this year that is not included in the series, because it is a recent admission and is still in the hospital. This occurred in a 6-year-old child developing an empyema following what appeared to be merely an upper respiratory infection. Cloudy fluid, positive for hemolytic streptococcus was obtained from the pleural cavity on admission. Four Gm of sulfanilamide daily were given by mouth. Although the fluid remained consistently positive, it was noted that the growth was retarded on the culture medium and did not appear for forty-eight hours. The sulfanilamide content of the chest fluid reached 6.6 mg per cent and the blood 9.7. The temperature reaction was effected little, if any, by the drug. Closed drainage was performed and convalescence is satisfactory.

Although no conclusions can be drawn from these facts, it is our intention to follow carefully future admissions in an effort to ascertain whether or not the incidence of empyema complicating streptococcal pneumonia in children is less than that which occurred in the years before the use of this drug. It is apparent that its effect is not uniform in all cases and it is likely there will be failures in any series of cases. We feel, however,

that it is possible to cure hemolytic streptococcal empyema in certain cases without drainage through the use of this drug and that convalescence may be shortened in cases that are drained. Delay while awaiting a cure should not preclude drainage to the point where the patient's life is endangered. Graham observes in commenting on the progress of thoracic surgery: "It seems probable also that the use of sulfanilamide in the streptococcal cases (empyema) may prove to be very beneficial."

The method of administration in our cases was only by mouth and intramuscularly. We have had no experience with the intrapleural method but feel that it might have some merit in certain instances, although the percentage of the drug in the pleural fluid can be raised to rather high levels without introducing it directly as shown in our recent case above reported. It has not been our experience to have ever seen a case of hemolytic streptococcal empyema spontaneously cured or to have them recover by aspiration alone. This fact gives added significance to the cures reported.

Sulfanilamide has been used also in the treatment of pneumococcal empyema. McIntosh reports 1 case of a type III infection, Basman and Perle report 2 cases of a type I infection without a favorable influence observed from the use of the drug. Bahrdt mentions no good results in pneumococcal empyema. Sulfapyridine has been used in the treatment of pneumococcal empyema. Barnett and co-workers report 2 cases due to type I pneumococcus and note a fall in temperature, decreased toxicity, general improvement of the patient, but in each instance the only effect observed on the fluid in the pleural cavity was that it thickened more slowly.

Flippin, *et al.*, in reporting 100 cases of typed pneumococcal pneumonia, treated with sulfapyridine, were interested in ascertaining the possible influence of the drug on the instance of empyema. They did not encounter this complication in any of the cases included in the report but in a later instance had

one case in which empyema developed, necessitating open drainage

My personal experience is limited to one instance, which was that of a child with type XIV pneumococcic empyema that was intensively treated with sulfapyridine. In spite of this the cultures remained positive. The interesting feature of this case was that the fluid was of a thin watery consistency with practically no sediment during treatment. Following discontinuance of the drug, it thickened over a period of two days so that the sediment reached 50 per cent and open drainage was instituted. This agrees with Barnett's findings and if borne out by future observations, should have an important clinical bearing on its use.

Discussion

Dr William J. Orr, Buffalo, New York—It should be noted in the cases just reported that empyema had already developed at the time treatment with sulfanilamide was instituted. In a limited experience, we have not observed that empyema developed in streptococcus pneumonia when sulfanilamide was started early in the course of the disease. Though this observation is made on a very limited number of cases, it may have a favorable significance in materially reducing the relatively high incidence of empyema following streptococcic pneumonia.

Since children tolerate sulfanilamide therapy

with very few unfavorable reactions, we have not hesitated to administer the drug in relatively large doses when the occasion warranted. About 1 gr. of the drug per pound of body weight is usually sufficient to raise the drug concentration in the blood from 8 to 12 mg. per 100 cc. In the cases of empyema just reported, similar doses of sulfanilamide were employed and the concentration of the drug in the pleural exudate ranged from 6 to 10 mg. per 100 cc.

Postponement of pleurotomy during the time the drug is being administered should have no adverse effect on the course of the disease even though in some instances it may be ineffective as it is usually employed during the period that one would ordinarily wait for the fixation of the mediastinum and the thickening of the exudate. If no favorable response is noted in the pleural fluid at the end of seventy-two hours of therapy, it is doubtful that further continuance of the drug will prove effective in promoting relief without pleurotomy.

Further continuance of the drug after pleurotomy, may have a favorable effect on the character and duration of the drainage.

In aspirating the pleural fluid, care was taken to withdraw only enough fluid to be used for a bacterial and chemical analysis. We did not wish to be accused of curing the patients by repeated aspirations of large quantities of fluid.

In the past few months, we have had an opportunity to observe the effect of sulfapyridine on the course of pneumococcus empyema. Six cases were treated with the drug after empyema had developed, with no favorable effect in the course of the disease. All cases received large doses of the drug. The concentration in the pleural exudate varied considerably from what we had observed in streptococcus empyema treated with sulfanilamide. Considerable difficulty was encountered in maintaining the concentration of sulfapyridine in the pleural fluid at a fixed level. Variations from a trace to 6 mg. per 100 cc. occurred. In no instance were we able to render the pleural exudate sterile, though the growth of organisms on culture media was materially reduced.

A phenomenon observed in all cases was a tendency for the fluid to remain serous and not thicken as is the rule in most cases of pneumococcus exudates.

Empyema did not develop in any of 30 cases of pneumococcus pneumonia that were treated with sulfapyridine. It is impossible to state just what significance this observation has in a small series of cases, but in a control series of a similar number of cases, 1 case of empyema had occurred.

DISTINCTIVE ODOR IN PATIENTS RECEIVING SULFANILAMIDE

SIDNEY LEIBOWITZ, M D , New York City

(From the Medical Service, Beth Israel Hospital, New York City)

DURING the past year, in patients receiving sulfanilamide a distinctive odor has been noted. This odor is most easily detected in the breath, but at times pervades the room and sometimes appears to be part of the general body odor. It can best be described as a fairly pleasant, sharp, fruity odor, somewhat akin to acetone but distinctly different from it and usually stronger.

At first this was a chance observation in a patient with meningitis receiving sulfanilamide. The odor was then thought to be due to acetone, but, interestingly, acetone was never found in the urine. This was true even in the case of 2 patients who were diabetic and who were being given sulfanilamide for other reasons. One of these patients, suffering from a type III pneumococcus pneumonia, was in diabetic ketosis shortly before the administration of the drug was begun, but at no time during the period that she received the drug (when the odor was noted) could acetonuria be detected.

After the first chance observation, the odor was looked for in patients receiving the drug and consistently it was found. The route of administration varied, some oral, some rectal. The time after ad-

ministration when the odor was first noted also varied from several hours to two days, so that a direct quantitative relationship is not necessarily indicated, although the dosage in these cases varied a good deal. In 1 case the patient had received only two doses of 15 grains when the odor was detectable when one entered the room. In this particular case, it was predicted that sulfanilamide had been given to the patient, a prediction that was verified by the patient's private physician. The odor seemed to disappear gradually over the course of one to three days after cessation of administration of the drug.

The cause for this odor is not known at present. In several patients the mouth hygiene was poor and the possibility of a local decomposition of the drug in the mouth suggested itself. But several patients presenting the odor showed an excellent state of oral hygiene. The drug itself is tasteless and odorless.

The observation may prove of some value. At least one practical application suggests itself in the possibility of detecting that the drug has been administered when one has no previous knowledge of the fact.

NOW HE MUST TAKE HIS MEDICINE

Mario Spino of 102 Third Avenue, New York City, said by police to have mulcted a number of physicians of various sums by fraudulent representations, was arrested in January following his apprehension by an alert doctor.

Specifically Spino is charged with stealing \$1,000 in silverware and furs from the home of Dr. Frank Discepolo of 95 Lexington Avenue.

Last December Spino went to the home of Dr. Discepolo and proposed that he become staff physician of an Italian society subsequently found to be nonexistent. A few days later Dr. Discepolo's home was entered and the furs and silverware—wedding gifts to the physician and his bride—were taken.

Detective Thomas Harris, suspicious that Spino had worked his spurious association game on other doctors, asked the Academy of Medicine to notify its members of Spino's racket. A description of the man was supplied.

Then Spino called at the office of Dr. J. C. Andriola at 231 Sherman Avenue. He gave his name as Mario Lombardi and invited the doctor to become the staff physician of his fraudulent society.

Recognizing Spino from the Academy's description, Dr. Andriola induced "Lombardi" to remain in his office while he slipped out, ostensibly on a short errand. Dr. Andriola returned with a patrolman and Spino was locked up.

one case in which empyema developed, necessitating open drainage

My personal experience is limited to one instance, which was that of a child with type XIV pneumococcic empyema that was intensively treated with sulfapyridine. In spite of this the cultures remained positive. The interesting feature of this case was that the fluid was of a thin watery consistency with practically no sediment during treatment. Following discontinuance of the drug, it thickened over a period of two days so that the sediment reached 50 per cent and open drainage was instituted. This agrees with Barnett's findings and if borne out by future observations, should have an important clinical bearing on its use.

Discussion

Dr William J Orr, *Buffalo, New York*—It should be noted in the cases just reported that empyema had already developed at the time treatment with sulfanilamide was instituted. In a limited experience, we have not observed that empyema developed in streptococcus pneumonia when sulfanilamide was started early in the course of the disease. Though this observation is made on a very limited number of cases, it may have a favorable significance in materially reducing the relatively high incidence of empyema following streptococcic pneumonia.

Since children tolerate sulfanilamide therapy

with very few unfavorable reactions we have not hesitated to administer the drug in relatively large doses when the occasion warranted. About 1 gr. of the drug per pound of body weight is usually sufficient to raise the drug concentration in the blood from 8 to 12 mg. per 100 cc. In the cases of empyema just reported, similar doses of sulfanilamide were employed and the concentration of the drug in the pleural exudate ranged from 6 to 10 mg. per 100 cc.

Postponement of pleurotomy during the time the drug is being administered should have no adverse effect on the course of the disease even though in some instances it may be ineffective as it is usually employed during the period that one would ordinarily wait for the fixation of the mediastinum and the thickening of the exudate. If no favorable response is noted in the pleural fluid at the end of seventy-two hours of therapy, it is doubtful that further continuance of the drug will prove effective in promoting relief without pleurotomy.

Further continuance of the drug after pleurotomy, may have a favorable effect on the character and duration of the drainage.

In aspirating the pleural fluid, care was taken to withdraw only enough fluid to be used for a bacterial and chemical analysis. We did not wish to be accused of curing the patients by repeated aspirations of large quantities of fluid.

In the past few months, we have had an opportunity to observe the effect of sulfapyridine on the course of pneumococcus empyema. Six cases were treated with the drug after empyema had developed, with no favorable effect in the course of the disease. All cases received large doses of the drug. The concentration in the pleural exudate varied considerably from what we had observed in streptococcus empyema treated with sulfanilamide. Considerable difficulty was encountered in maintaining the concentration of sulfapyridine in the pleural fluid at a fixed level. Variations from a trace to 6 mg. per 100 cc. occurred. In no instance were we able to render the pleural exudate sterile, though the growth of organisms on culture media was materially reduced.

A phenomenon observed in all cases was a tendency for the fluid to remain serous and not thicken as is the rule in most cases of pneumococcus exudates.

Empyema did not develop in any of 30 cases of pneumococcus pneumonia that were treated with sulfapyridine. It is impossible to state just what significance this observation has in a small series of cases, but in a control series of a similar number of cases, 1 case of empyema had occurred.

in children because of parental ignorance play such an important role in the precipitation of behavior problems of childhood, its chief concern must of necessity be with the pre-school child and with parental education

Now what about the special techniques utilized in child guidance work? In order to open discussion of this often-asked question we should like to refer to a definition of mental hygiene formulated some years ago by the late Dr Frankwood E Williams, for many years director of the National Committee for Mental Hygiene, who said, "Mental Hygiene is the art of application of knowledge derived from certain basic sciences to the maintenance of individual mental health. Mental health should not be interpreted too narrowly as merely freedom from disease but broadly in the sense of behavior and the ability to attain and maintain satisfactory human relationships. This ability depends upon the potentialities of the individual for physical, intellectual, and emotional growth on the one hand and opportunities for growth on the other" [*Mental Hygiene* 11 (No 3) (July) 1927]

Child guidance, therefore, is not a science. For its working knowledge it calls on several sciences. In the light of such scientific knowledge it attempts to understand the individual and his capacities in the several panels of his total personality as well as the opportunities and limitations of the environment in which he lives. Hence the need for the utilization of the many agencies and institutions which comprise that environment in order to achieve a successful solution for the individual's problems. We might therefore say, insofar as it uses available scientific information, child guidance is scientific, and that its technic is a cooperative or combined technic.

One might well be asked, "Specifically, what types of cases or problems are the natural concern of these clinics?"

Many uninformed individuals have the mistaken idea that the clinic is interested in and useful for only the mentally defective. While the facilities afforded by

a clinic may lend themselves admirably well for mere diagnosis of mental deficiency, the scope of its purpose is much broader, as it concerns itself with the utilization of educational, industrial, and social settings which make possible a satisfactory adjustment in the community in spite of the mental deficiency. Hence, its interest in special educational programs for the abnormal or backward child.

The problem of mental deficiency is, therefore, not a major concern of the clinic.

A much more interesting group are the children with no intelligence defect but who express their maladjustments by delinquent behavior. In these cases the function of the clinic is to gain a thorough understanding of the personality of the child from a study of his instinctive, emotional, intellectual, social, and biologic life, and the relationship of these to his offense and to attempt to evaluate them as to whether they are assets or liabilities with special reference to rehabilitation.

Only a well-organized child guidance clinic is prepared to carry out such a comprehensive handling of the situation.

And more important still than the two groups just mentioned are the perhaps more common and certainly more neglected group which shows only minor conduct disorders or who may be said to have personality traits which, although not producing definite antisocial behavior, nevertheless do bring them into more or less serious conflict with the environment.

We believe that personality traits result from the attempt of the child to solve his problems.

The trait so established, if satisfactory to him and to those about him, may be considered a healthy one. If this is not so, conduct disorder results and naturally the greater the number of unhealthy traits present and the smaller the number of compensatory, healthy, or balancing traits present, the more does the behavior lean toward delinquency.

Needless to say, the earlier these undesirable traits are corrected the more favor-

THE FUNCTION OF A CHILD GUIDANCE CLINIC

HARRY A. STECKEL, M D, Syracuse, New York

(Director, Syracuse Psychopathic Hospital)

NEEDLESS to say, I deem it a privilege to be afforded the opportunity to present a paper on child guidance before the section on Public Health, Hygiene, and Sanitation. To me, it is most pleasing, because it indicates that the work of the founder of the mental hygiene movement in this country has not been in vain and that after some thirty years the prevention of mental diseases assumes the same importance to our public health officials as do physical hygiene and sanitation. Without doubt, it bespeaks a superlative vision and a broad concept of purpose on the part of those same officials which augurs well for the future of all our public health activities.

One gets the impression that mental hygiene as a movement was impeded by the fact that it originated in the field of psychiatry—for so many years regarded as a stepchild of medicine—and that it was therefore, as such, not always too gently or sympathetically treated. Today, however, there seems to be a growing recognition of the important part which the emotions, mental attitudes, and environmental stresses play in the total reactions of the human being, that more and more the psychiatric or psychobiologic point of view creeps into the practice of medicine and now finds itself welcomed into the field of preventive medicine.

In view of the fact that the child guidance clinic looms large in any community mental hygiene program, a definition of what such a clinic is seems in place at this point of our discussion.

A psychiatric clinic which devotes its time exclusively to work with children is generally designated as a child guidance clinic. Its chief aims and purposes are the diagnosis and treatment of the be-

havior and personality problems of childhood.

Such clinics have been a natural outgrowth of psychiatry, since our study of psychoses and their beginnings in the adult has revealed the fact that the personality defects which lead to psychosis are the result of faulty training during the early formative period of life and that therefore any worth-while effort at prevention must begin before pernicious pattern reactions are too firmly set.

The field of preventive activities is not, however, confined to mental disorders alone, for educators, criminologists, and social workers in many other fields in their efforts toward prevention have found need for the type of service afforded by the child guidance clinic.

The primary function therefore of the clinic is to correct mental deviations in their incipency, to establish a mentally healthy environment for the child, and to promote among adults a better understanding of the needs of the child for healthy mental development.

In order to accomplish this broad purpose the clinic tends to develop its own resources and organization, to study and treat the more difficult individual problem cases, and to help the community to deal with the less complex problems through its own already existing resources.

Inasmuch as many behavior problems are caused by social or environmental factors rather than by personality difficulty inherent in the individual, it can readily be understood why the clinic must rely upon many social groups and organizations in the community in the final adjustment program of the child. Furthermore, because parental ignorance and early attitudes and habits produced

*Read at the Annual Meeting of the Medical Society of the State of New York,
Syracuse, April 26, 1939*

more directly contributory to the deficiency, than his inherent endowment

5 Children with *early* organic defects or toxic reaction types

6 Children with specific disabilities

The importance of early diagnosis and treatment which Dr Steckel has stressed cannot be overemphasized. The value of adequate thorough case recording as preparation for a scientific approach, long-term study, and future reference cannot be denied.

Dr Albert B Siewers, *Syracuse, New York*—Fifty years ago medicine made rapid strides under the influence of the concept of cellular pathology. Psychiatry got lost in the shuffle, as more than 50 per cent of the psychiatric cases have no cellular pathology to go with it. A new discipline had to be developed, and it is no better exemplified anywhere than in the work of a child guidance clinic.

The preventive aspect is certainly a most im-

portant one, and the influence of the clinic on the environment might well deserve a little further consideration. "Ability to bear children does not carry with it the ability to bring them up." The mother who is in contact with the child guidance clinic on account of one child learns something which she might apply to the rest of her children, or in her philosophy of living.

I from personal prejudice, feel that the school system is the proper place for a child guidance clinic, and certainly a psychiatric hospital which deals with prevention, is also a proper place for a child guidance clinic. In any given situation, it is simply a matter of working in with the existing setup in such a way as to provide the community what it needs in the way of child guidance and preventive psychiatry. As "childhood is the golden age of mental hygiene" a preventive program must be applied as early as possible. The nursery school might well develop into a prechild guidance clinic.

WORKMEN'S COMPENSATION

THE following plan of procedure was recommended by the Industrial Council at its meeting held on January 8, 1940, in cases where a difference of opinion exists between the attending physician and the examining physician employed by the employer or insurance carrier, as to whether or not further treatment is required.

1 The employer or insurance carrier must exercise their right to have a medical examination made of a compensation claimant by their medical examiner, on which a direction to the attending physician to stop treatment must be based.

2 A request forwarded to the attending physician to stop treatment must be accompanied by a report of the medical examiner employed by the employer or insurance carrier setting forth the physical findings.

3 If the attending physician does not agree with the findings of the medical examiner, he must arrange to confer with the medical examiner for the purpose of reaching an understanding.

4. If the attending physician and the medical examiner are unable to agree, a joint examination of the claimant should be arranged for the purpose of comparing the findings of both the attending physician and the medical examiner.

5 If an agreement cannot be reached on the joint examination, arrangements should then be made to refer the claimant to a mutually agreeable consultant.

6 When a difference of opinion still exists in such cases where the above procedure is followed, such cases shall be referred to the Department of Labor for medical examination or for a hearing at which the attending physician or the consultant shall be subpoenaed to appear by the Department of Labor.

In any case where all the physicians agree that no further treatment is necessary, but where the patient himself demands further attention, procedure No. 6 is recommended. Please report to your Workmen's Compensation Committee any failure on the part of an employer or insurance carrier to cooperate.

DAVID J. KALISKI, M.D., *Director, Bureau of Workmen's Compensation,
Medical Society of the State of New York*

able the prognosis. Hence, the greater interest of the child guidance clinic in the preschool child as compared to the older age groups.

And this consequently leads us to the consideration of parental guidance and education as, in a way, a byproduct, yet strictly speaking, a primary and important function of the clinic.

Parents are a most important component part of every child's environment. Because of the responsibility which parents assume in the nurture and admonition of the growing child and the many pitfalls which present themselves in child training, the importance of parenthood can be readily recognized, yet very few make any serious effort to prepare themselves for this most important job in the world.

Many parents take the stand that self-defeating traits appearing in their children are the result of inherent disposition or arise from physical or nervous defects which cannot be altered. Some may try to obtain scientific information from the many modern psychological schools of thought and become involved in a maze of contradictory theories which only tend to confuse them.

And finally, the larger number of parents merely drift along, assuming that competent parenthood is a sort of mysterious endowment which nature presents to them as an accessory talent upon the arrival of the child. The fallaciousness of this assumption is only too evident, and parents should be encouraged to attempt some earnest and real preparation for this all-important work.

Certainly, no better source of reliable information on the scientific training of children can be found than the child guidance clinic, as here the parent will be advised not in generalities but upon a strictly individualistic basis with due regard for all factors involved in the specific parent-child relationship.

Furthermore, in view of the constant contact which the clinic makes with social agencies in the community the workers of these organizations are constantly sensitized to the psychiatric point of

view so that they too become more effective as they approach their jobs with psychobiologic insight.

Hence we recognize the educational feature of the clinic as one of its most important functions.

In conclusion, may I say how happy I am to have had this opportunity of welcoming the prospect of a closer union between psychiatry and preventive medicine, recognizing of course, the child guidance clinic as an outgrowth of the psychiatric point of view and emphasizing childhood as the most fertile field in the prevention of mental disorder as well as in the matter of progressive and scientific human engineering.

In this brief paper I have tried to outline the outstanding purposes and functions of a child guidance clinic. It will be self-evident that such a clinic becomes a potent factor for good in any social group, large or small, and that every progressive community should make it a component part of its public health program.

Discussion

Dr Eugene Davidoff, *Syracuse, New York*—I am appreciative of the opportunity to discuss Dr Steckel's timely contribution. Dr Steckel has amply demonstrated the importance of the mental health of the child in relation to the more general aspects of his hygiene and has crystallized these early influences, which, until recently, physicians have been aware of only moderately.

I wish merely to reiterate Dr Steckel's remarks concerning the various types observed in the early stages of development where some measure of success has attended efforts at readjustment.

- 1 The child with early personality and emotional disorders in which the child yields to his more infantile impulses in adjusting to environmental influences—the neurotic child.

- 2 The child who attempts to protest against environmental as well as infantile emotional forces but who has arrived at a faulty, socially frowned upon, more primitive solution—the child with early delinquent traits.

- 3 The child who is influenced by poor economic and social conditions.

- 4 The mentally defective child—where the environmental and emotional influences are

tain the greatest efficiency and health, we must adjust, to a greater or less extent, the food (fuel) of the body to the occupation (work)

Our food, after eating, undergoes digestion, fermentation, and putrefaction. The undigested, unassimilated protein residue undergoes alkaline putrefaction, the undigested residue of the carbohydrates and fats undergoes acid fermentation. The proper balance, therefore, must be definitely maintained between the food materials (proteins, fats, and carbohydrates) to prevent the preponderance of overacidity or overalkalinity within the intestinal canal. An improper food adjustment results in autointoxication and disease. Unfortunately, most people eat too much of one or the other of these foodstuffs. A properly balanced diet will chemically and physiologically balance itself within the intestinal tract.

The normal fermentation within the stomach, brought about by the bacteria present within that organ, is definitely and commonly known to be the result of the activities of the various acid-forming bacteria. Lactic acid is, by most authorities, considered to be a normal acid of the stomach, because of its constant presence. Butyric acid is formed in milk during gastric digestion as the result of the action of the *Bacillus butyricus*, after lactic acid is formed. Alcohol is changed within the stomach by the action of the fungus of acetic acid (*Mycoderma aceti*) into aldehyde and acetic acid. Glucose is acted upon by yeast (*Saccharomyces cerevisiae*) and split into carbonic acid gas and alcohol. These examples of fermentation show that bacterial action enters into the cause of different types of fermentation within the stomach. The action of certain bacteria present in the gastrointestinal tract probably is part of the physiologic workings of these organs, and part of what we assume to be the normal digestion of different nutrient material.

We may presume that there is more or less injury to the inside of the intestinal canal from the presence of bacteria, food, and toxins. The cause of the injury then, we believe, lies, not so much within the

intestinal wall, as in the intestinal content.

The indefinite pathologic, etiologic, and clinical classification of the diarrheas of infants has provided a confusion of therapeutic procedures. Observation, in many instances after death due to severe alimentary diseases, will show that there were seldom marked changes in the intestinal mucosa, and that the pathology of the intestinal wall had less to do with the fatal termination than severe toxicity. The production of so-called food injury with "protein intolerance," "carbohydrate intolerance," or "fat intolerance," all of which are supposed to be definite gastrointestinal phenomena associated with excessive peristalsis, can only be due to an improper intestinal flora.

Commonly, excessive acidity with rapid peristalsis will indicate an undue fermentation of the carbohydrates and also show the presence of undigested proteins and fats. A strong laxative may produce an artificial food intolerance, and as a result there will be found present all three of the food classes, in varying stages of digestion.

Bacteria are living organisms which require food for their existence, which must be of a kind most suitable for their nutrition. Those which thrive best on proteins produce an alkaline end product, which favors the development of bacteria requiring that reaction, and the type which grows most favorably on carbohydrates produces an acid end product which is most suitable for bacteria which thrive in an acid medium.

The prognosis of an inflammatory appendix may be dependent upon the virulence of the type of bacteria predominating within the intestinal tract to a greater or less extent, because of the culture medium provided by the previous variety of food and its imperfect digestion. An excessive protein diet will produce a preponderance of either streptococci, staphylococci, or *B. welchii*, and a too abundant diet of carbohydrates will produce an acid type of intestinal content favoring the development of colon bacilli. The biologic action of the *Bacillus butyricus* on fats may increase fermentation

THE RELATION OF FOOD TO NONSPECIFIC ULCERATIVE COLITIS

MARTIN L. BODKIN, M.D., F.A.C.S., Brooklyn, New York

(Consultant, Rectal Surgery, St. Catherine's Hospital, Brooklyn)

THE etiologic factors giving rise to the simple catarrhal diseases of the intestine are considered, generally, as the result of deficient physiologic action, directly or indirectly, which is followed by pathology within the intestine. Our clinical knowledge is most perfect but the origin of these common diseases is indefinite and dependent largely upon the laboratory for further elucidation.

Metchnikoff popularized the idea of introducing desirable types of bacteria into the intestinal canal when the beneficial types were inactive, or of re-enforcing the weakened residual type with suitable cultures in the form of Bulgarian buttermilk. The Bulgarian bacillus was selected because of its ability to produce a large amount of lactic and other acids without gas. The lactic acid produced was thought to be inhibitory in its action to the development of putrefactive organisms that are claimed to be retarded by acids.

This theory, however, is open to question, because acclimatization of the Bulgarian bacillus to the intestinal contents of man has been found impossible. The *Bacillus acidophilus*, a lactic acid-producing organism, is theoretically and practically the only parasite that we can logically select from the normal intestinal flora of the adult human being for its protective influence.

The Eskimos, living in a desolate unproductive area of the earth, are restricted mostly to the consumption of animal food. Their diet, devoid of the starches and sugars, offers a problem that presents contradictory evidence very interesting and unsolved as to intestinal bacteria.

The presence and propagation of the many indigenous bacteria in the atmosphere of the temperate zones that are favored by warmth, moisture, and an

abundance of suitable culture mediums can hardly be present in the extreme low temperatures of the arctic region and they are probably free from the destructive activity of these bacteria.

However, the study of the stratosphere which has recently shown us that bacteria are carried from parts of our country, miles high over intervening lands, to distant portions of the globe, may reveal some interesting discoveries among the Eskimos.

If we accept the theory of the existence of intestinal toxemia, then we must believe that autointoxication is brought about by abnormal digestive material which insidiously causes more people to suffer from premature senility, sickness, and death than any other factor. While alcoholism, infections, contagious diseases, and accidents are responsible for some of our human ills, consider the host of diseases such as rheumatism, arterial sclerosis, allergic, kidney, cardiac, appendicular, colonic, nerve, skin, and many other ailments that are directly or indirectly due to a derangement of the gastrointestinal tract, beginning as simple physiologic disturbances which result in disease.

The result of physiologic digestion is heat and energy. The chemical ingredients of the proteins, fats, and carbohydrates are vitally essential to life and form the ordinary diet or fuel upon which we have learned to subsist. A proper selection of these three foods is necessary.

Therefore, our food must be of a proper variety and quantity to be easily digested and assimilated to obtain the greatest efficiency in the bodily functions. Proteins are concentrated foods, easily digested and oxidized, the carbohydrates and fats are more slowly digested and assimilated. For these reasons, to ob-

hydrates presents symptoms of over-acidity, heartburn, sour-smelling feces with alternation of constipated or diarrheal movements, gas distention, red, swollen, or fissured tongue, headache, sour stomach, and malaise. Examination of the stool will reveal acid reaction and overpreponderance of Gram-negative bacteria of colon type. There will be a history of a lack of protein diet. They partake of either vegetables or non-meats such as cereals, vegetables, and fruits, and of fats in the form of meat soups and rich milk. The fats exaggerate the fermentation.

Feces Examination from Smear

Reaction ?

Gram-negative percentage?—(Normal 75 per cent)

Gram-positive percentage?—(Normal 25 per cent)

Bacterial types and relative percentage?

As an example the normal findings from a smear would be approximately as follows

Reaction	pH	7 0
Gram-neg percentage		75 per cent
B coli		65 per cent
Gram-neg diplococci		10 per cent
Gram-pos percentage		25 per cent
Anaerobic		15 per cent
Gram-pos diplococci		10 per cent

The proteolytic type very often presents sudden symptoms of toxicity sometimes without diarrhea. There may be coated tongue, foul breath, chill, rise in temperature, and obstipation. When this type presents itself in a less severe or chronic form, these symptoms of auto-intoxication persist over a long period, generally associated with constipation and its sequelae. The flora shows a decided preponderance of Gram-positive bacilli, alkaline in reaction, including *Bacillus aerogenes capsulatus* and *Bacillus lactis aerogenes*, the staphylococcus and streptococcus are also to be noted. Toxic albumoses may be found to produce auto-intoxication, including vasomotor disturbances caused by the products of imperfect protein metabolism.

The treatment of the nonspecific type of colonic diseases has become a biochemical problem from the observations of the bacteriologists. From Kendall,

Hertter, Rettger, and many others who have studied the relation of food to bacteria in the intestinal canal, we draw conclusions that proteins, fats, and carbohydrates enter the intestine and are changed by the action of ferments, bacteria, and heat to become end products of nutrient material, besides many known and unknown chemical combinations and toxins. The presence of amino acid, histidine, and the toxic amine histamine is due to bacterial action. The *B coli* acting upon amino acid tryptophane produces indol. Bacterial activity on certain sugars produces formic acid, and the *B coli*, acting on formic acid, results in sodium formate, and if the bacterial activity persists, a final conversion to sodium carbonate results.

In view of these findings, a strong presumption is warranted that we are correct in following the dictates of experience to the effect that the variety of food eaten for our sustenance is also nutrient material for certain types of bacteria, and that these bacteria cause chemical disintegration which yields known products.

It has been my experience that implantation of the *B acidophilus*, by excessive feeding or by instillation through the rectal tube, will fail. The benefit of either method is temporary if the proper pabulum is not introduced into the alimentary canal in the form of food, because the desired bacterial growth will not become permanent. The fundamental principle of feeding the patient for the propagation and stabilization of these bacteria within the intestine is necessary.

The chemical reaction also enters into the inhibition and growth of bacteria as already stated, so that the meat eater can be benefited by taking lactic acid solutions in the form of buttermilk, or acidophilus milk, which prevents the growth of putrefactive bacteria. The fermentor undoubtedly suffers from the overproduction of lactic acid and should eat less food which produces acids—counteract acidity by eating more than the habitual quantity of meats (proteins). Overeating of fats in any form will increase overacidity or overalkalinity and

or putrefaction but will not initiate either

Normal Flora

B coli

staphylococci

B welchii

Abnormal Flora

I Saccharolytic

Abnormal carbohydrate diet (mixed or nonprotein)

End product excessively acid

Gram-negative stain shows large number of B coli group

B coli in greater number than

B acidophilus staphylococcus

B welchii

B mesentericus

Diplococci

II Proteolytic

Abnormal protein diet

Excessively alkaline

Gram-positive stain shows greater number of bacteria taking gram-positive stain

Gram-negative shows color group lesser number

B mesentericus staphylococcus

B welchii

B coli — the latter as pure putrefactive bacteria

Streptococcus

Diplococci

Fat diet may increase either putrefaction or fermentation of intestinal contents

Normal end product acid

The intestinal bacteria are prolifically propagated within the intestinal canal where conditions are most favorable for their growth, and there is no more ideal, combined incubator and culture medium conceivable to the bacteriologist. These bacteria procure their food within its walls and excrete their waste products into the intestinal canal

Breast-fed infants supply the most perfect flora from which the study of the intestinal contents of human beings can be fundamentally made because of its simplicity. This type is constantly do-

minated by the *Bacillus bifidus* with a mildly acid flora and, therefore, presents the standard for investigation, whereas, following an increase of proteins there will result a lessening or suppression of the *Bacillus bifidus* and *Bacillus acidophilus*. Conversely, an increase of carbohydrates will cause a diminution in proteolysis

When a child is not breast fed and a modified feeding substituted, we have introduced a food of relatively high protein and variable sugar contents that may be compared with adult food and the bacterial action will result in a type of flora much the same as is presented from the mixed diet. The changed food produces an entirely different growth of bacteria from the previously fed breast milk with its protecting harmless beneficial flora. These bacteria commonly make the intestinal tract of artificially-fed infants the recipient of nature's reproach by their great proliferation. The variety of bacteria thus cultured has never been determined by our bacteriologists

Kendall regards the intestinal flora as a physiologic unit rather than a collection of bacteria and states that the common colon bacillus forms 75 per cent of the bacterial contents. This latter portion of his statement, that 75 per cent of the bacterial contents is composed of Gram-negative bacteria, has been proved by my investigations

In the adult, the *Bacillus mesentericus* and *B coli* are found to be the most persistent of the intestinal bacteria. The flora are classified generally as the facultative (normal), fermentative (acid), and proteolytic (alkaline)

Porter and others classify the types of inflammatory diseases of the intestine among children as follows: mild, fulminating, grave, chronic, and putrid diarrhea. These types are presented in the adult identically as Porter and his co-workers have found them

The differential diagnosis of the types of the intestinal flora varies with the amount of proteins, fats, and carbohydrates taken as food and the subsequent proper or improper digestion of these essential foods. Overindulgence in carbo-

Case Reports

THE RELIEF OF SOME CASES OF EYE DISCOMFORT

HOMER L. BRYANT, A.M., M.D., Rockville Centre, New York

(From the Eye Department, Jamaica Hospital, New York City)

MANY persons who have normal vision i.e., 20/20, with or without correction, suffer some eye discomfort. In some of these cases aniseikonia (asymmetry of visual images) is thought to exist but has been shown not to be present. Such cases have been relieved by the correction of a small amount of astigmatism which existed, although they had 20/20 vision.

Persons who use their near vision a great deal, such as school teachers, are mostly affected. Soon after using their eyes for near vision, headache, eye ache, photophobia, and reading discomfort appear.

General Discussion

It is the author's opinion that this reading discomfort is caused by the eye attempting at all times to produce the best possible image on the retina. Because of the small amount of astigmatism, the eye is constantly focusing in first one meridian and then another in an attempt to produce the best image. It is this constant focusing that brings about the symptoms described herein.

In practically all of these cases nervousness is a prominent symptom.

Since all these cases are alike as far as symptoms are concerned, only 2 case reports will be given.

Case Reports

Mrs. M. B., white, schoolteacher, aged 38, complained of extreme eye discomfort when correcting school papers. She had been refracted many times and has very acute vision, with no astigmatic correction.

Her complaints were that after using the eyes for near vision, headaches, eye ache, extreme photophobia, and reading discomfort became so bad that she would have to stop her work and rest her eyes.

It was thought that, because of the patient's acute vision with no astigmatic correction, aniseikonia existed. She was examined thoroughly for aniseikonia which was found not to be present. However the symptoms continued.

The author refracted her under homatropine, and found a slight amount of astigmatism in each eye, which was corrected.

She took the following prescription O.D. plus 1.12 combined with plus 0.25 \times 80, O.S. plus 1.12 combined with plus 0.25 \times 110.

Vision was 20/20, with or without the astigmatic correction, but was a little more distinct with the astigmatic correction. She was given her full correction and her symptoms were relieved.

Mrs. R. M., white, aged 34 was a minister's wife who did a great deal of reading and fancy work.

Her symptoms were extreme nervousness, photophobia, headaches and eye aches. She had been refracted to 20/20 vision, her glasses contained only a plus 0.25 cylinder for each eye.

She was refracted under homatropine and was found to take the following correction O.D. plus 1.25 combined with plus 0.50 \times 135, O.S. plus 0.87 combined with plus 0.50 \times 40.

She was given her full correction, which corrected all her astigmatism, and since then she has been relieved. Her nervous condition also improved markedly.

Conclusions

The author is satisfied that a correction of 20/20 vision does not always properly correct the patient or make for eye comfort. It is important to examine these cases carefully for astigmatism and correct any small amount which might be present.

In other words, 20/20 vision does not necessarily mean comfort. The author noted, in practically all of these cases, a change in the disposition (personality) of the persons, especially an improvement of their nervous condition.

must be taken sparingly except by those whose labor is very hard

The human body is a machine, and, in order to function properly, needs a definite kind and individual quantity of fuel for its vitality and ultimately to create energy, just as the man-made machine can only consume a definite quantity of fuel in the attainment of its maximum efficiency

In other words, it matters little as to the quality of the food we eat if properly balanced and we select a variety of foods which are digestible. A perfectly digested meal will result in only a small undigested residue to serve as a culture medium for a harmful number of bacteria

Summary

1 The presence of bacteria within the intestinal canal is beyond question

2 The entrance of bacteria from outside the body, in relatively small numbers,

is also undoubted, but the propagation and stabilization of bacteria within the bowel, over long periods, show that their existence is dependent upon the contents of the intestinal canal

3 Animals select their own kind of food and vary their diet only through necessity and parasitic life behaves in a similar manner in choosing its food

4 The cultivation of the different types of bacteria is not dependent upon the food we eat and digest properly, but upon that portion of the food we eat and do not digest properly. It is this undigested, unassimilated portion that affords a favorable pabulum for bacterial consumption

5 Logically it stands as a fact, that we can lessen or increase the relative proportion of intestinal bacteria by an unbalanced or undigestible diet. Therefore, if we change the diet, we change the bacterial contents

Annual Meeting

May 6, 7, 8, and 9, 1940

New York City

THE Waldorf-Astoria is the headquarters. Special rates have been arranged of \$6 to \$8 for single rooms with bath, and \$9 to \$11 for double rooms with twin beds and bath. Reservations should be made at the earliest moment in order to secure these low-priced rooms. Attention of the membership is called to the fact that the various sessions follow one another very closely, and therefore those who register at headquarters will run no risk of missing any portion of the meetings.

The Scientific Program and the description of exhibits, both scientific and technical, will appear in the April 1, 1940, issue of the *New York State Journal of Medicine*. This year the booklet program will not be mailed, but copies will be available for all who attend the meeting.

Certain Scientific Exhibits may be installed beginning Friday, May 3, but all must be in place by noon, Monday, May 6. It is necessary that all be removed not later than noon of Friday, May 10. Any information desired by exhibitors may be secured from Dr. Byron E. Farwell, 122 East 76th Street, New York City, the local member of the committee in charge. His telephone number is RHineland 4-3727.

All members should register at the desk in the Silver Corridor. In past years a number have neglected to do this, and it is essential that the record be full and accurate.

PETER IRVING, M D
General Manager

Fig 3 Lateral view of chest on March 9, 1937, eight days after admission, showing the encapsulated empyema on the right posterior wall.

Fig 4 Lateral view, taken on same day as Fig 2. Study of this roentgenogram, and of the one illustrated in Fig 3, strongly suggests an encysted posterior wall empyema, which has partially emptied, showing a fluid level.

The first plate (Fig 1) was described as an early lung abscess. All early anterior-posterior views were interpreted as lung abscess (Figs 1 and 2). Lateral views, however (Figs 3 and 4), indicated that we were probably dealing with an encysted posterior wall empyema, which had ruptured into a bronchus. Subsequent roentgenograms showed gradual clearing. Fig 5 is one taken five months after discharge from the hospital, and illustrates complete healing with no apparent pulmonary or pleural residua.

Summary

An acute encysted pyothorax, located on the right posterior chest wall and complicated by bronchopleural fistula, responded favorably to conservative treatment by oral drainage. The roentgen findings simulated the appearance of a lung abscess.

BRONCHOPLEURAL FISTULA

A Report of a Case Complicating an Encysted Pyothorax with Unusual Roentgen Findings

BERNARD L PACELLA, M D, and GEORGE E BROCKWAY, M D, Brooklyn, New York

(From the Department of Pediatrics, Kings County Hospital)

BRONCHOPLEURAL fistula complicating acute pyothorax is reported to have an incidence of 10 to 15 per cent.^{1,2}

Bettmann and Crohn,² and Broadbent,³ observed that nearly all empyemata which rupture into a bronchus are interlobar.

Roch,⁴ and others,^{2,3} concur in the opinion that surgery is usually necessary in the treatment of this complication.

This case is reported because it is an example of a bronchopleural fistula complicating an encysted empyema which was not an interlobar collection, but was located on the posterior wall of the thorax, because of the unusual roentgen findings which resembled a lung abscess, and because of the complete recovery with conservative treatment by oral drainage.

Case Report

A white boy, aged 11 years, was admitted to the Kings County Hospital, March 1, 1937. He complained of a painful, dry cough and fever. These symptoms appeared suddenly seven days prior to admission. The onset was preceded by two days of headache, loss of appetite, fatigue, and vomiting.

On admission, the boy's temperature was 102 F, pulse 130, respirations 34, chest examination disclosed a moderate impairment to percussion, diminished tactile fremitus, and bronchovesicular breathing over the right lower lobe. The heart was not enlarged nor was there any shift in its

position. Our diagnosis was an incompletely resolved pneumonia accompanied by thickened pleura.

On March 4, three days after admission, the boy complained of severe pain in the right mid axillary region, which radiated to the angle of the scapula. The pain was accentuated with cough and deep respirations. At this time there were definite physical signs of a right pleuritic effusion. In 48 hours, the pain subsided.

On March 8, 1937, the cough became productive, and there was frequent expectoration of mucopurulent sputum. A bronchopleural fistula complicating an encysted effusion was suspected. A 1 per cent methylene blue solution was injected into the right pleural cavity, and within four minutes a blue-stained, purulent sputum was expelled. The purulent expectoration continued in gradually diminishing amounts until March 16 when it ceased entirely. The patient rapidly improved and convalescence was uneventful. On March 25, 1937, physical and roentgen examination of the chest revealed normal findings. A follow up study for one year revealed no subsequent abnormal lung or pleural findings by physical or roentgen examination.

The roentgen findings illustrate how readily they can be confused with those of a lung abscess.

FIG 1 AP view taken March 2, 1937, one day after admission into hospital. Note the suggestion of abscess formation with fluid level on right.

FIG 2 AP view taken March 11, 1937, ten days after admission into hospital. There is a marked increase in the size of the apparent abscess formation on the right. Fluid level can still be seen.

Hearings

Feb 20 { S Int. 134—Warner }
 { A. Int. 152—Milmoie } Sale of fireworks—joint hearing before Codes Committees

There follows a list of the bills taken up by the Legislative Chairmen's Conference on February 7, with action indicated upon each bill

Approved

Legislative News

Bulletin No 5

(February 9, 1940)

New Bills Introduced

SENATE Int 842—Kleinfeld, requires New York City Education Board to establish child guidance bureau Referred to the Education Committee

COMMENT Same as Assembly Int 461, reported in Bulletin No 3 Disapproved by Chairmen's Conference

Senate Int 856—Graves, Assembly Int 1106—G F Daniels, requires a permit from the State Health Commissioner for sale of ice cream after inspection of cows, barns, and manufacturing equipment, to determine that sanitary conditions and milk standards are maintained, also requires permit for importing evaporated or condensed milk sold in hermetically sealed cans when intended for use in manufacture of ice cream, fees are imposed for the expenses of inspection Referred to the health committees

COMMENT Disapproved by Chairmen's Conference.

Senate Int 927—Page, provides that applicants for medical licenses who meet requirements as to preliminary and professional education with evidence of successful practice or professional experience and with evidence satisfactory to State Education Commissioner that they have been duly licensed in another state or territory of the United States, may receive licenses without further examination, provision relating to applicants who matriculated in New York State medical school before June 5, 1890, being stricken out Referred to the Education Committee

COMMENT The Department of Education suggests that an amendment which would require that the credentials of every person applying with a license from another state for its endorsement be thoroughly studied, including the preliminary education and professional education, as well as the questions and rating of the licensing examination, to see that both of those were equivalent to what was required in New York State at that time This will terminate automatic reciprocity and will very likely decrease the annual number of licenses endorsed

Senate Int 968—Phelps, Assembly Int. 1219—Wagner, provides that after July 1, 1941, instead of 1940, it shall be unlawful to practice nursing without being duly licensed and registered, increases from 7 to 12 the minimum membership of state board of examiners for nurses, with four to be selected from each of three lists submitted by certain nurses' organizations, and makes other changes. Referred to the education committees.

Referred to the education committees.

COMMENT The three nurses' organizations mentioned are the New York State Nurses' Association, which is authorized under the law at present to submit lists, and to this is added the Nurses' Union and the American Federation of Registered Nurses The bill was not acted upon by the conference because printed copies were not available for study

Assembly Int 1117—Wagner, requires that city education boards and school districts maintaining vocational schools, shall provide health service for pupils attending vocational high schools, with necessary personnel to afford physical examinations and x rays Referred to the Education Committee.

COMMENT The Chairmen's Conference approved of this measure except that portion which requires that all of the children be x rayed as to their chests They felt that children in vocational schools should have the same advantages as children in high schools, and since x raying of the chest is not required but is being done voluntarily in some schools, they felt that no such requirement should be included in this bill

Assembly Int 1122—Shaw, provides for free treatment of persons suffering from poliomyelitis by local health authorities, where person is unable to pay for such care, one-half of cost is to be paid by county or in New York City by the city and the other half by the State, \$30,000 is appropriated Referred to the Ways and Means Committee.

COMMENT Disapproved by the Chairmen's Conference.

Assembly Int 1126—Quinn, requires druggist or pharmacist, upon request, to furnish a true and complete copy of a refillable prescription to the person for whom it was filled Referred to the Codes Committee.

COMMENT Disapproved by the Chairmen's Conference

Assembly Int. 1181—Goldstein, makes it unlawful for agent or officer of public hospital to refuse to admit private patients willing to pay for facilities or to deny licensed physician or surgeon permission to attend and prescribe for any patient therein Referred to the Codes Committee.

COMMENT This bill was not available for consideration by the Chairmen's Conference on Wednesday, but identically the same bill was before the Legislature last year and was disapproved by the committee.

"THE FOUNDATION PRIZE" AWARD

The rules governing the award of "The Foundation Prize" of the American Association of Obstetricians, Gynecologists, and Abdominal Surgeons are as follows

1 The award which shall be known as "The Foundation Prize" shall consist of \$150

2 Eligible contestants shall include only (a) interns, residents, or graduate students in obstetrics, gynecology, or abdominal surgery, and (b) physicians (with an M D degree) who are actively practicing or teaching obstetrics, gynecology, or abdominal surgery

3 Manuscripts must be presented under a nom-de-plume, which shall in no way indicate the author's identity, to the Secretary of the Association together with a sealed envelope bearing the nom-de-plume and containing a card showing the name and address of the contestant

4 Manuscripts must be limited to 5000 words, and must be typewritten in double spacing on one side of the sheet. Ample margins should be provided. Illustrations should be limited to such as are required for a clear exposition of the thesis. Submit three copies of thesis and illustrations to the Secretary

5 The successful thesis shall become the property of the Association, but this provision shall in no way interfere with publication of the communication in the journal of the author's choice. Unsuccessful contributions will be returned promptly to their authors

6 All manuscripts entered in a given year must be in the hands of the Secretary before June 1

7 The award will be made at the annual meetings of the Association, at which time the successful contestant must appear in person to present his contribution as a part of the regular scientific program, in conformity with the rules of the Association. The successful contestant must meet all expenses incident to this presentation.

8 The President of the Association shall annually appoint a committee on award, which, under its own regulations shall determine the successful contestant and shall inform the Secretary of his name and address at least two weeks before the annual meeting.—JAS R. BLOSS, M D, *Secretary*, 418 Eleventh Street, Huntington, West Virginia

BEATS ELECTRIC BELTS

Struck by lightning in January, a California justice of the peace says it cured his arthritis. Quite a lot of folks have had all their troubles ended by this treatment.

ON A FALSE SCENT

A doctor says he can tell a lot about patients by the shape of their nostrils. But we expect there have been occasions when he has made wrong diagnoses.—*Punch*

County News

Albany County

Dr Conrad Wesselhoft, associate professor on communicable diseases at the Harvard Medical School and Harvard School of Public Health, spoke on "Advances in Management of Infectious Diseases" before the scientific session of the Albany County Medical Society in the Albany Pharmacy College on January 24.

The discussion following Dr Wesselhoft's talk was opened by Dr Otto A Faust and Dr Charles K. Winne, Jr.

Chemung County

Although adequate medical and dental care is available in Chemung County if requested, city physicians are overworked and cannot give sufficiently close care to people on relief, there is too much routine required before hospital service can be obtained by relief patients and the situation is complicated by new relief laws and additional burdens, there are sufficient medical facilities for indigents of the community, but borderline-income groups suffer.

These are some of the conclusions of a just-completed county-wide survey of the medical needs of Chemung County. The study was conducted by a committee from the Medical Society of Chemung County and the Health Division of the Elmira Council of Social Agencies at the request of the American Medical Association. Chemung County was selected as a test spot in this district, results to be included in a national survey of medical needs and recommendations.

Approximately 273 question blanks were submitted to institutions and organizations concerned with health work in the county.

Less than half responded by supplying answers, a fact which prevents results from being conclusive.

Those contacted and total returns compare as follows: physicians and dentists, 106 contacted 35 replies, hospitals, 5, 4, nurses, 5, 4, health departments, 15, 3, welfare and relief agencies 32, 15, schools, 9, 9, colleges, 1, 1, pharmacists, 23, 16, other organizations, 77, 29.

To meet the needs discovered, some of those questioned favor voluntary sickness insurance, particularly for the middle class and poor not on relief, others believe that the work now done by the city physicians should be returned to private physicians at reduced fees.

Replies would indicate that hospital facilities are ample but that members of marginal income families do not receive adequate nursing care. Many, it is reported, forego such care rather than ask for free service.

An exposition of syphilis—its dangers known remedial measures, and responsibilities of the layman in curtailing its spread—was given for approximately 130 guests at a social hygiene dinner on January 31 at the Mark Twain Hotel in Elmira by Dr Paul Padgett, syphilologist, instructor, and national consultant in syphilis from Johns Hopkins School of Medicine.

The dinner was jointly sponsored by the social hygiene committee of the Visiting Nurse and Tuberculosis Association and the Chemung County Medical Society in observance of the fourth annual Social Hygiene Day.

Dr Padgett was introduced by Dr George R Murphy, president of the county medical society. Dr Ross G Loop, chairman of the medical advisory committee of the visiting nurse association, presided.

Erie County

Formal opening of offices of the Non-Profit Western New York Medical Plan at 374 Delaware Avenue, Buffalo, and receipt of its operating permit from the New York State Insurance Department have placed the medical plan on the list of going concerns.

The new offices are in the Huyler Building and adjoining those of the Blue Cross Hospital Service Plan, the field staff of which will handle enrollment of subscribers throughout the area. Operating procedures will parallel those of the hospital plan, subscribers being accepted only on a payroll deduction basis.

Complete medical and surgical care is provided under the plan, with the following rates applying individual subscribers, \$18, for indemnification up to \$200, man and wife, \$27, for \$300 coverage, entire family (husband and wife and all unmarried children under 19 years of age), \$36, for \$400 coverage.

All payments for service are made directly to the participating physician by administrators of the plan and the physician's receipted bill is given the subscriber in satisfaction of the benefits due him under terms of his contract. These payments are computed on the basis of an official schedule of reduced fees and prorated on a unit basis.

Guarantee of subscriber benefits is made by the participating physician, who agrees to provide specified service regardless of the plan's ability to pay.

The acting board of trustees, consisting of twenty-five, includes sixteen physicians and nine laymen who were the original incorporators of the plan. They all serve without pay. The permanent board will be elected by the participating physicians and its membership will have such geographic distribution as is prescribed in the bylaws.

Included on the present board are prominent laymen throughout the Eighth Judicial District, in the eight counties of which the medical plan is chartered to operate: four past-presidents of the Erie County Medical Society, the president of the Buffalo Board of Health, and other leading physicians and surgeons of the district.

Under the welfare department's medical plan the state will reimburse Erie county 40 per cent of expenditures not exceeding \$82,100, Harold S Tolley, state area welfare director, told the county welfare board on February 8.

The plan calls for payment to physicians for

medical services for welfare clients At present hundreds of physicians treat welfare cases without being recompensed

"Experience in other cities and states would indicate that adequate care could be provided for an amount not in excess of \$46,800," Tolley said "However, since the board has decided that the proposed plan better meets the needs of Erie County and is preferred regardless of possible higher costs, it seems reasonable to cite maximums beyond which no state reimbursement should be expected"

They are Physicians' fees, \$38,300, salaried physicians, \$9,600, pharmacists, \$5,600, drugs, \$6,400, and additional administrative staff, \$22,200

The area director declared no reimbursement could be expected from the state until the entire plan is in operation

Local welfare officials estimated the medical plan would cost \$146,000 annually

A symposium on anesthesia was presented by the Buffalo Academy of Medicine at its meeting on February 7 An allergy program was given on February 14

Chancellor Samuel P Capen announces that approximately \$425,000 has been provided for a new medical school building at the University of Buffalo

Dr Capen announced a gift of \$200,000 from Mrs DeWitt H Sherman, in addition to a bequest estimated at \$225,000 by her late husband, Buffalo pediatrician, whose will was offered for probate on February 7

Dr DeWitt Halsey Sherman, Buffalo pediatrician who died on February 1 at the age of seventy-five, had served for twenty years as professor of pediatrics in the University of Buffalo Medical School Dr Sherman was secretary and later president of both the Buffalo Academy of Medicine and the Erie County Medical Society He was an organizer of the New York State Medical Society and the fourth chairman of its section of pediatrics

Genesee County

An interesting offer was made by the Genesee County Medical Society to the city of Batavia in January, whereby relief families would be permitted to summon a physician of their own choosing, thus doing away with the office of city physician.

Headed by Dr Peter J Di Natale as chairman, the special medical society committee offered to handle welfare medical and surgical needs for \$4,300—the sum spent by the city for that purpose last year The committee would have prorated payments to physicians on the basis of services rendered

Also on file was a request from Dr Homer A Harvey, the city physician, for a salary increase from \$1,500 to \$2,250

Dr Harvey's salary last year did not include the cost of major operations or medical supplies, items which the physicians' committee covered in their \$4,300 proposal.

The common council, however, on February 7, turned down the physicians' offer and reappointed Dr Harvey at a salary of \$2,000

Dr George Critchlow of Buffalo, chairman of the Western New York Medical Indemnity

Insurance Corporation, spoke at a special meeting of the Genesee County Medical Society on February 8 in Batavia at the Hotel Richmond on the medical insurance plan offered to members of the Genesee County society

Herkimer County

The Medical Society of the County of Herkimer met at the Mohawk Valley Country Club on February 13 A scientific program was prepared by Drs Shults, Vickers, and Lill The latter made an address and Dr H van Z Hyde, of Syracuse read a paper on pneumonia

Jefferson County

The regular monthly meeting of the Medical Society of Jefferson County was held at the Black River Valley Club on February 8 There was a symposium on welfare by Ray S Dunaway, A E Cole, and Miss Angie L Kellogg A moving picture on "Trichomonas Vaginalis" was shown and was discussed by Dr James L Crossley There was a tumor clinic at Mercy Hospital at 5 00 P M

On January 6 the Black River Valley Club tendered a dinner for Dr Grosvenor S Farmer in honor of his ninetieth birthday There were over one hundred friends, many of them physicians, who attended the party Dr Farmer has been a member of this club for sixty years and still conducts some medical practice

Kings County

The forty-second annual meeting of the Associated Physicians of Long Island was held on January 27, at the Brooklyn Hospital

The scientific program at 10 00 A M comprised operative clinics in various departments of the hospital, 12 00 o'clock noon, inspection of the hospital, 1 00 P M, guests of the hospital at luncheon

At 2 00 P M the scientific session was held, at which the following papers were read and discussed "Conservative Surgery in the Treatment of Acute Osteomyelitis," Dr Ainsworth L Smith—Discussion, Dr Carl Hettesheimer "Thyrototoxicosis in Pregnancy," Dr J Thornton Wallace—Discussion, Dr Austin Johnson "Tendonitis of the Tendon of the Long Head of the Biceps Brachii Muscles," Dr Donald E McKenna—Discussion, Dr Frank S Child "Carcinoma of the Larynx—Demonstration of Patients Using Artificial Larynx," Dr Robert L Moorhead—Discussion, Dr Henry B Smith "The Diagnosis of Cardiovascular Syphilis—An Analysis of 20 Cases to Necropsy," Dr Edwin P Maynard Jr—Discussion, Dr Eugene Calvelli

At 4 00 P M, there was a business meeting and election of officers At 7 00 P M, the annual dinner was held at the Montauk Club, 8th Avenue and Lincoln Place, Brooklyn

After the dinner a travel talk, illustrated with lantern slides, was given by Commander Frank W Ryan, Medical Corps, U S N, on "A Medical Man's Experiences in Samoa"

Dr Joshua Marsden Van Cott, president of the professional staff of the Brooklyn Hospital since 1930 and president of the board of trustees of the Hoagland Laboratories attached to the Long Island College Hospital, died on February 8 at his residence, 160 Henry Street, Brooklyn, at the age of seventy-eight.

He was a founder and fellow of the American College of Physicians, chairman of public health and education of the New York State Medical Society, 1912-1924, and vice-president of the same society, 1927-1928. He had been president of the Medical Society of the County of Kings in 1909, and in 1913 served on the advisory committee of the New York Board of Health. He was also a founder of the Associated Physicians of Long Island.

More than two hundred doctors attended an educational forum on February 5 under the auspices of the East New York Medical Society at the Temple Auditorium, Rochester Avenue and St. John's Place. Dr. Hyman I. Teperson, president, was chairman.

Development in the methods of treating the hard of hearing was discussed by several eminent physicians.

Dr. William Stevenson Applegate, a pioneer physician in Flatbush, where he practiced from 1887 until his retirement in 1913 and for fifty years a member of the Medical Society of the County of Kings, died on February 6 in his home on Vail Road, Parsippany, N. J., at the age of eighty-seven after an illness of three months.

When Dr. Applegate retired to devote his time to farming he was president of the Flatbush Medical Society.

Shortly before his death Dr. Applegate presented his medical books to the Medical Society of the County of Kings.

Madison County

The regular winter meeting of the Madison County Medical Society was held at the Hotel Oneida Oneida, on January 18. A dinner preceded the business and scientific session.

The program was as follows: "The Vaginal Discharge," by Sydney W. Stringer, "The Early Local Care of Traumatic Wounds, with Special Reference to Wounds of the Face," by Dr. Leon E. Sutton, "A Treatise on Vitamin Deficiencies," by Dr. Earle E. Mack, all of the above from Syracuse, and a "Technicolor Film on Physical Diagnosis," by Dr. Ernest Freshman, of Oneida.

Monroe County

Dr. John R. Murlin, University of Rochester physiology professor, was the principal speaker at a joint meeting of the Monroe County Medical Society, the Rochester Academy of Medicine, and the University of Rochester Medical School in the academy's auditorium, on January 28.

Dr. Murlin's subject was "The Place of Vitamins in Normal Nutrition." There was also a special showing of a sound motion picture. Dr. Murlin is director of the university's vital economic department.

Nassau County

The scientific program of the Nassau County Medical Society on January 30 was as follows: Topic and Speakers "Visualization of the Chambers of the Heart and of the Thoracic Blood Vessels" (A New Diagnostic Method) 1—Clinical Application in Heart Disease" by Dr. George Porter Robb, visiting physician, Cardiac Clinic, New York University College Clinic, clinical assistant visiting physician, Bellevue Hospital, instructor in clinical medicine, New York University College of Medicine 2—

"Its Practical Value in Lung Disease," by Dr. Israel Stenberg, chief, Chest Clinic, Bellevue Hospital, chief, Chest Clinic, New York University College Clinic, instructor in medicine, New York University College of Medicine, physician-in-chief, Consultation Chest Clinic Department of Health, New York City (Kips Bay-Yorkville District).

The topic on February 27 was "Endocrinology in the Female," by Dr. Robert T. Frank, of New York, and the topic on March 26 will be "The Treatment of Arthritis, Practical Suggestions for the General Practitioner," by Dr. Loring T. Swaim, of Boston.

The Rockaway Medical Society celebrated its seventeenth anniversary on February 1 at Lawrence Village Park Inn, where a dinner was served. About seventy-five doctors from the Rockaways and neighboring Nassau villages attended. The evening was given over to sociability. There was no formal program.

"We cannot help feeling a sense of satisfaction in reviewing Nassau County's diphtheria record for 1939. Three cases were reported in January and 1 each during April, June, and October, making the county record a mere 6 cases for the entire year compared with 14 for 1938 or an average of 27 for the five years before 1939. Comparing a record of 6 cases and no deaths with one of 208 cases and 12 deaths in 1928, we are forced to the conclusion that the energetic campaign against diphtheria which has been waged by the county medical society since 1928 is, at least in part, responsible for this very dramatic improvement.

The present thinking among health authorities is that every child should be given at least two doses of toxoid at the age of nine months or as soon as possible thereafter. Then every child should be given another dose of either plain toxoid or alum precipitated toxoid at about the time of entering school."—*Nassau Medical News*

Onondaga County

A paper was presented at the meeting of the Onondaga County Medical Society on February 6 on "Obstruction of Alimentary Tract in Infants," by Dr. Samuel W. Clausen, pediatrician-in-chief of Strong Memorial Hospital and Rochester Municipal Hospital, professor of pediatrics of the University of Rochester School of Medicine and Dentistry. Discussion was opened by Dr. A. B. Raffil.

Dr. Frederick S. Wetherell was guest of honor at a dinner given by the staff of the *Bulletin* publication of the Onondaga County Medical Society and the Syracuse Academy of Medicine on January 23, in appreciation of his efforts and service as editor of the publication for three years.

During these first three years Dr. Wetherell did most of the work of reporter, editorial writer, advertising department, and editor. The *Bulletin* began as an eight-page publication published in Rochester, and has evolved to a booklet of twenty-eight pages with a circulation of 1,000 doctors and hospitals in central New York and is printed in Syracuse.

Dr. Wetherell is chairman of the publications committee of the Onondaga County Medical Society and, in his twenty-fifth year of connection with the staff of St. Joseph Hospital, is

president of that staff. He is a member of the publication committee of the *New York State Journal of Medicine*, and is a former member of the medical economics committee of the state society.

Dr Morris Fishbein, editor of the *Journal of the American Medical Association*, and Dr John Peters, professor of medicine of Yale University, discussed "The National Health Problem" at the Mizpah Auditorium on February 26, under the auspices of the Town Hall of Syracuse, Inc. An open forum was held at the end of the meeting.

The Syracuse Housing Authority has honored the medical profession of Onondaga County and its society by naming one of its pioneer courts in memory of John Howell Frisbie, first president of the Onondaga County Medical Society.

Queens County

The program of the Medical Society of the County of Queens on January 30 included "The American Health Program," by Dr Nathan B. VanEtten, president-elect, American Medical Association; "The Doctor Looks at the Citizen," by Dr Terry M. Townsend, president, Medical Society of the State of New York.

Friday afternoon talks included February 2—"The Use and Abuse of Dehydrating Agents in the Treatment of Head Injuries," by Dr Jefferson Browder, neurosurgeon, Long Island College, Brooklyn, Kings County hospitals; February 16—"Office Dermatology," by Dr Howard Fox, dermatologist, New York, Bellevue, Lenox Hill, Knickerbocker hospitals.

Orange County

Featured speakers at a health meeting in Goshen High School auditorium on February 13 were Dr Terry M. Townsend of New York and Dr Frederic J. Elliott.

Sponsored by the Twentieth Century Club of Goshen, the meeting was open to the general public. Also assisting in arrangements were the Orange County Medical Association and Orange and Rockland County Hospital associations.

Dr Theodore W. Neuman of Central Valley, chairman of the county medical group's public relations committee, presided.

Dr Townsend, president of the state medical society, spoke on "Socialized Medicine," and Dr Elliott on "Medical Indemnity Insurance." Dr Elliott is secretary-treasurer of the Medical Expense Fund, Inc., which is organizing doctors for the insurance plan.

Oswego County

Dr Newton Cook, of Sandy Creek, who died at his home on January 7, had practiced medicine there since 1880.

Schenectady County

Dr Joseph E. Connery, professor of hematology at New York University Medical School and attending physician at Bellevue Hospital, was the speaker at the meeting of the Schenec-

tady County Medical Society at Ellis Hospital on February 6. Dr Connery spoke on "Types, Diagnosis and Treatment of Anemia." He illustrated his talk with lantern slides.

There was a special luncheon meeting of the Schenectady County Medical Society on February 1, in the cafeteria of the Ellis Hospital, to hear Dr Paul W. Harrison, F.A.C.S., of Arabia, on "Surgery Under Desert Difficulties." Dr Harrison has been a medical missionary for twenty-eight years, and has been responsible for pioneer work on hemorrhaphy and spinal anes thesia. He is the author of "The Arab at Home," and has been recently described in magazine articles as "The Desert Doctor."

Suffolk County

Cancer was the subject of the meeting of the Suffolk County Medical Society on January 31 at Friede's Inn at Smithtown.

Wayne County

The Wayne County Medical Society met on February 6 at the Hotel Wayne in Lyons and devoted the meeting to a discussion of pneumonia.

The speaker was Dr Henry van Zile Hyde. Dr Hyde is a member of the Pneumonia Speakers' Committee appointed by the Medical Society of the State of New York. He discussed the recent progress in treating pneumonia, especially with regard to serum treatment and sulapyridine.

Westchester County

In the February issue of the *Westchester Medical Bulletin*, published by the county medical society, is a question addressed to the profession, but one in which all persons in this county, as well as throughout America should be interested, remarks the Tarrytown News. Here it is:

"Will American medicine soon be faced with the necessity for civil disobedience in the public interest?"

"It may be the only possible alternative in view of the political trend toward national socialism in this nation. Faced with a choice between regulation by its own code of ethics or obedience to embarrassing, encroaching, onerous, sumptuary, or even hostile legislation conceived for the advancement of social reforms, but in practice too restrictive of medical freedom of thought and action, what will the profession do?"

"The question must be answered."

In that answer will lie a most serious thought, says the Tarrytown editor, for not only the medical profession but the millions whom it serves.

Dr H. G. V. Hunter was elected president of the White Plains Medical Society, at a special meeting January 30 at the Contemporary Club.

Other officers elected were Dr J. R. Montgomery, vice-president, Dr Harry Klapper, secretary-treasurer, and Dr Robert Towse and Dr Granville Knight, new governors for two years.

"Young Dr Jones seems to have considerable earning power."

"Yes, he does, but it doesn't equal his wife's yearning power."—*Rocky Mt. Medical Journal*

Across the Desk

The Hard-Headed Yankee Nation Turned into Rainbow Chasers

LIFE is so hard nowadays that people believe some magic must and will turn it soft overnight. We are so dazzled by the myriad luxuries of civilization that we think we can live like kings on a dollar down and a dollar a week. Advertisements scream at us to come and borrow money. Not one rainbow but a thousand turn our sky to a blaze of glory, and the pots of gold seem in our inflamed imagination so plentiful as to make Fort Knox look like the poorhouse. No wonder the clever politicians have the nation running around in circles expecting Utopia by the wave of a wand.

The hocus pocus of today's "professional political charlatan," was the theme of a trenchant address before the Medical Society of the County of Kings on February 20 by Dr. Terry M. Townsend, president of the Medical Society of the State of New York, under the title, "Who Shall Lead the Leaders?" It seems that Dr. Townsend has been looking at the American citizen, and "it would be funny," he remarks, "were it not tragic, to trace the history of his befuddlement by one after another sweet singer of halcyon songs, who have played upon his weakness." For instance "First, we were to have a managed currency, to bring back prosperity, then, we were to have control of farm products, with plenty of money for the farmer through higher prices for his products, then unemployment was to be banished, we were to have peace and justice between labor and capital through a labor relations board. I do not need to weary you with the long list of ideal plans for perfecting this and that, all of which looked promising on paper but not one of which succeeded in practice in doing what it set out to do. There was one defect in all these plans. They left out the little matter of changing human beings in such a way as to permit the schemes to work. Now we have the newest hopeful promise—the others having failed—government medical care for all, with everybody healthy and relieved of the necessity for paying for it."

Thimblengging the Citizen

Why is it, Dr. Townsend wonders, that when all these rainbows fade, the citizen still seems eager to be fooled by each new plan? He believes it is because these schemes offer the citizen an escape from the hard realities of life, just as phantasy does. They save him from realizing that the fault "is not in our stars, but in our selves that we are underlings." The citizen wants to believe he can work less and earn more, save less and have more, go in debt and not have to pay it. Even when the schemes fail, we do nothing, remarks Dr. Townsend. Why don't we turn the schemers out? The reason is significant. It is because "it is easier to think that we cannot do anything about it than to think that we can. Effort is avoided, and effort is painful. Most of us are seeking an easy way out of our problems."

Thimblengging the citizen is a clever game that goes merrily on, year in and year out. We are suavely assured by our leaders that we are living

under a 'democracy.' A radio program promoted by government agencies is styled, "Democracy in Action." A meeting has just been held in Washington on "Children in a Democracy." But, declares Dr. Townsend, "We are not living in a democracy at all, we are living under a form of representative government," and the representatives we elect, and who make our laws generally have but one guiding idea—to be re-elected. The people rarely, if ever, have the chance to vote on public measures—the very essence of democracy. The Washington "conference" on "Children in a Democracy" was all 'framed weeks in advance', the material "was prepared by those who had their own special cause to plead, and no chance was given for all who might disagree with the points made, to prepare and present a contrary view." In a word, the conference may have been a good thing, but 'it was not democratic, and did not deal with 'children in a democracy.' "

Nations in Padded Cells?

The psychiatrist could size up our rainbow chasers in ten seconds. The psychiatrist tells us, says Dr. Townsend, that the insane act as if no accomplishment were impossible, they recognize no limits to the granting of their needs, and they admit no authority or opinion so good as their own. When their environment refuses to alter at their command, 'they take refuge in escape mechanisms to relieve the conflict. They cannot stand reality, so they take flight from it.' "

Not all the insane are in hospitals, remarks Dr. Townsend meaningfully, but, fortunately, not naming any names. Perhaps he includes us all when he observes that "everyone, to some extent, flees certain realities." But he would not cart us all to the asylum, for it is only when the mechanism which is substituted for reality becomes dangerous to others or to the patient himself, that he is removed from society."

But wait a moment, do not feel too safe. A whole nation may go gaga, to use a low form of expression. As Dr. Townsend more elegantly puts it, "Now there is a collective mechanism of escape as well as an individual one, we may have mass delusions, mass escapes." There is a mob psychology, strangely irrational, that has been often noted and mass reactions were never so common as today." Television will give an added weapon to the spellbinder and the demagogue who wish to incite the nation to pursue this or that will-o'-the-wisp. Unfortunately," adds Dr. Townsend, there is no way to put whole nations into padded cells. They have to run riot until the crowd disease has spent its force."

You and I may think at once of some other nations, far, far away, that ought to be put in a cell with large pads and no exits, but it is only too evident that he means us. If we doubt it, that is just another of our delusions. And he knows no cure. "I hesitate to think," he says "that I could possibly know how to prevent what seems to be the operation of natural laws

Civilization moves in cycles. Man builds up his complex life, becomes corrupted by luxury, destroys his own civilization and weakens himself in so doing, goes again into darkness, to rebuild, after centuries, perhaps. Seeking, struggling, restless, foolish MAN!"

Problem of a Cure

Materialism may be the root cause of the disease, hazards Dr Townsend. People are debating, quarreling, fighting about material possessions. If materialism is the cause, then spirituality, the very opposite, is the thing to counteract it. If greed and selfishness drive nations mad, rouse hatreds, ring the tocsin, and loose the dogs of war, then can we falteringly suggest that spirituality might be the antitoxin? Perhaps that would not be permissible. Dr Townsend states it better in these words:

"There are those who like to think that man is primarily a spiritual creature, and that the main purpose of living should not be to obtain goods and chattels, lands and buildings, but to attain to the good life, which is the inner life, as well pursued in poverty as in riches. False values, false goals, false ambitions, and, of course, false realizations, are the result. It is not a mere coincidence that in many countries where the people have been robbed of their freedom they have also been deprived of their churches.

"If there be a cure for the existing disorders, it may come when a courageous leader arises who will tell the people that the hard, thorny path to the only Utopia we can ever have on earth requires that we be honest and not evasive with ourselves, our problems, and our fellow man.

We cannot really escape our problems for the very good reason that *we* are our problems, each man is his own problem, each group is its own. When we accept these difficulties, instead of trying to escape them, and try to make ourselves more worthy, try to *give* more, rather than *get* more, perhaps the way out will be made clear."

Pendulum Swings Both Ways

Various historical writers have noticed the interesting fact that the life of nations proceeds, as Dr Townsend notes, in cycles. The ebb of our moral tide is followed by a reverse flow, as day follows night and summer follows winter. Action and reaction are equal and opposite. After one era of political corruption a man of rocklike integrity was elected to one office after another in this state and then to the presidency so swiftly that when he went to Washington to be inaugurated it was the first time he had seen the city. After another, the youngest President ever elected rode into power on a wave of idealism and righteousness, while politicians sneered that he had "discovered the Ten Commandments." After a favorable word he had spoken, vendors stood on street corners of New York City and sold quantities of Pastor Charles Wagner's book, *The Simple Life*. Such are the revulsions of feeling in our land of the free. It is not at all impossible that at this moment, somewhere between our eastern and western seas, the courageous leader that the president of our State Society is looking for is forging the sword that will win the battle for all of us.

NUMBER 6

Editorial

The Wagner Hospital Bill

Two bills have been introduced in Congress in response to President Roosevelt's recent message on hospital construction. Senator Mead's measure includes hospital construction among a number of other projects for which federal loans are authorized. That sponsored by Senator Wagner closely follows the pattern of the President's message. Of the two the Wagner bill appears to have a more comprehensive grasp of the problem and a more precisely conceived solution.

Unlike other medical legislation proposed in recent years, the Wagner bill acknowledges the differences in medical needs in different localities. It promises hospitals only to communities requiring them and vests administrative power in the hands of local authorities.

In other words, a community would have to demonstrate its need before receiving a federal hospital. There would be no indiscriminate construction to compete with local institutions. Once built, the hospital would be leased to the community, maintenance and operation serving in lieu of rent.

Also to be praised are the provisions for expert supervision and consultation. The United States Public Health Service, not a lay bureau, is charged with responsibility for selecting hospital sites, approving construction plans, formulating standards of maintenance and operation, receiving reports, making inspections, and generally safeguarding the quality of service rendered. To prevent "political" administration and give the Surgeon-General the benefit of professional knowledge and experience outside official life, the bill creates a national advisory council of six members to be chosen from pre-eminent medical and scientific authorities. This advisory group would consider and recommend all applications for hospitals and collaborate closely with the Surgeon-General in the formulation and maintenance of satisfactory operating standards.

As the bill stands now, the advisory council would have considerable influence but no authority. More positive functions and a greater measure of control would increase its usefulness and mitigate the enormous responsibility placed upon the Surgeon-General.

Some of the provisions of the new Wagner bill are of questionable wisdom, for example, that combining "protection of the public health" with the duties usually entrusted to a hospital. These are minor matters, however, which can undoubtedly be adjusted in view of the approval the major provisions of the bill command.

Indeed, in this measure Senator Wagner appears to have avoided most of the faults of his so-called national health bill. Where the former called for enormous expenditures for theoretical, vaguely defined purposes, the hospital bill appropriates the relatively small sum of \$10,000,000. No large institutions will be built. Construction will be kept on a small scale until the program has had an opportunity to demonstrate its practicability and value.

As suggested above, the Wagner bill could be improved by increasing the powers of the advisory council, omitting functions not usually performed by hospitals, and providing for local medical participation in the approval of sites. On the whole, however, this measure adheres to the principles laid down by the medical profession for federal aid and will receive hearty support from the nation's physicians.

On the other hand, further clarification is in order regarding one portion of this bill. In Sections 9 and 10, there are provisions for additional commissioned officers and other personnel and *provision for the training of this personnel*. If an increase in the personnel of the United States Public Health Service is desired, Congress should explicitly be asked for it. Such a "rider" should not be included in this particular bill.

It is also important to know whether these hospitals are to be turned over to the doctors of the community to treat the sick of the area surrounding them, or whether the Public Health Service of the Federal Government is planning to fill them with its personnel. Perhaps this is but a thinly disguised effort to expand government medicine, allowing it to compete with private medical practice. Should this be the case, it must be made known to all of us. Before organized medicine takes any definite action in support of this bill these questions must be answered.

Up to YOU

Although the State Legislature has power to alter the form and scope of medical practice, few physicians bother to communicate their views to their representatives at Albany. This apathetic atti-

life shows a surprising indifference to the fate of their profession. There are many occasions on which an unmistakable expression of professional opinion would have a decisive effect on the course of legislation affecting medicine. Yet the average practitioner is satisfied to sit back and let outside influence shape his destiny.

Politicians (and legislators are necessarily politicians) respond to the expressed will of the voters. When a group of citizens fails to make its wishes known, legislators cannot be blamed if they obey the mandate of more attentive voters. In this respect the voice of the individual is more effective than that of organizations. The legislator knows that he is elected by the ballots of individuals in his district and then opinions, therefore, count most heavily with him.

Physicians must learn to exercise their full political power in the interests of their profession and the public health. At the present time there are two measures pending in Albany which should be passed this year and can be if individual practitioners get behind them and push. The Desmond-Vincent bill gives needed statutory protection to the practice of radiology. The Page-Milmoe bill regulates the endorsement of medical licenses granted in other states. Passage of these bills would strengthen the educational foundations of medicine by excluding unqualified technicians and graduates of inferior schools elsewhere from practice in this state.

There is no important opposition to either of these methods. Their adversaries can be shown to be more interested in obtaining or preserving advantages to which they are not entitled than in furthering the public welfare. Nevertheless, it is safe to predict that the will of a selfish minority will prevail unless the medical profession makes its voice heard.

Physicians have no right to complain of legislative apathy when they themselves are too indifferent to their own interests to make their views known to their representatives. The state and county medical societies are unceasingly active at Albany but they cannot carry the entire burden of legislative campaigning.

Make the Desmond-Vincent radiology bill and the Page-Milmoe medical license bill a test of your political influence. Write, by phone, or telegraph at once YOUR representative in favor of these measures.

Some Common Sense

Medical literature is replete with advertisements. These columns, as well as the editorialized progress which these columns have achieved. But, amid the voluminous advertisements which these achievements, there is only one

As the bill stands now, the advisory council would have considerable influence but no authority. More positive functions and a greater measure of control would increase its usefulness and mitigate the enormous responsibility placed upon the Surgeon-General.

Some of the provisions of the new Wagner bill are of questionable wisdom, for example, that combining "protection of the public health" with the duties usually entrusted to a hospital. These are minor matters, however, which can undoubtedly be adjusted in view of the approval the major provisions of the bill command.

Indeed, in this measure Senator Wagner appears to have avoided most of the faults of his so-called national health bill. Where the former called for enormous expenditures for theoretical, vaguely defined purposes, the hospital bill appropriates the relatively small sum of \$10,000,000. No large institutions will be built. Construction will be kept on a small scale until the program has had an opportunity to demonstrate its practicability and value.

As suggested above, the Wagner bill could be improved by increasing the powers of the advisory council, omitting functions not usually performed by hospitals, and providing for local medical participation in the approval of sites. On the whole, however, this measure adheres to the principles laid down by the medical profession for federal aid and will receive hearty support from the nation's physicians.

On the other hand, further clarification is in order regarding one portion of this bill. In Sections 9 and 10, there are provisions for additional commissioned officers and other personnel and *provision for the training of this personnel*. If an increase in the personnel of the United States Public Health Service is desired, Congress should explicitly be asked for it. Such a "rider" should not be included in this particular bill.

It is also important to know whether these hospitals are to be turned over to the doctors of the community to treat the sick of the area surrounding them, or whether the Public Health Service of the Federal Government is planning to fill them with its personnel. Perhaps this is but a thinly disguised effort to expand government medicine, allowing it to compete with private medical practice. Should this be the case, it must be made known to all of us. Before organized medicine takes any definite action in support of this bill these questions must be answered.

"Will American Medicine soon be faced with the necessity for civil disobedience in the public interest? It may be the only possible alternative in view of the political trend toward national socialism in this nation. Faced with a choice between regulation by its own code of ethics or obedience to embarrassing, encroaching, onerous, sumptuary, or even hostile legislation conceived for the advancement of social reforms, but in practice too restrictive of medical freedom of thought and action, what will the profession do? The question must be answered.

"In their haste to bring about social reforms, many of which are desirable and some few of which may well be attainable in time, legislators are constantly importuned to drive the wedge of positive law further into the domain of the unenforceable. Particularly is this true of legislative onslaughts on medicine.

"The code of ethics of the medical profession is the only law which can be recognized by physicians within the domain of the unenforceable. The unenforceable is 'that which you should do although you are not obliged to do it.' The unenforceable is the motivation of the art of healing. It should not be commanded, it cannot be driven, it must not be compelled. Yet the public welfare law seeks to regulate it. Compulsory health insurance seeks to shackle it—has enchained it in many European countries. It is not of those things 'which are of a kind fit to be regulated by government.'

"Will the legislators of this nation force the medical profession into civil disobedience?

voice which beseeches "common sense" in the *practice* of medicine. Such is the article by Summers¹ concerning the practice of pediatrics.

He terms the pediatrician "a general practitioner for children." The desperately sick child (and every child is desperately sick at the beginning of any illness) will in most instances recover by the institution of sound symptomatic treatment and "watchful waiting." Thus, he claims, holds true for almost 99 per cent of sick children. For the others, in particular those afflicted with diphtheria and severe scarlet fever, specific therapy must be instituted promptly, and these ailments are readily recognized by any physician.

The management of fever in a child, the dietary needs during illness, the importance of a planned regime in the period of recuperation, and the strict attention to cleanliness and nursing care will, more often than not, bring about the cure of a sick baby. Spectacular therapy, while useful and efficacious in the selected case, cannot and should not be applied to the ordinary everyday illnesses which occur in the lives of all children.

Here again is strong support for the continuance of individualization in the practice of medicine as a necessity for the furtherance of the public health.

Sulfamethylthiazol

So much work has been done in the development of sulfanilamide and its allied compounds and in the clinical application of these drugs to combat the diseases caused by the pneumococcus and streptococcus, that one no longer registers surprise when still another offspring of the parent compound is reported as effective against the staphylococcus. The addition of the thiazol radical to sulfanilamide has produced sulfathiazol, and its methylated derivative is sulfamethylthiazol which, from experiments *in vitro* and *in vivo* is a more efficient agent against *Staphylococcus aureus* than either sulfapyridine or sulfanilamide.

Staphylococcic bacteremia has always been accompanied by a high mortality rate until the advent of these drugs. With this new compound Herrell and Brown² obtained recoveries in 4 cases of infections due to this organism. 2 cases of severe cellulitis, 1 of lobar pneumonia, and 1 of a fulminating staphylococcic septicemia. The new drug appears clinically to be less toxic than sulfapyridine which also is valuable in the treatment of staphylococcic infection. In their preliminary report on the use of sulfamethylthiazol, Herrell and Brown advocate as the dosage 2 grams for two doses at four-hour intervals, and then 1 gram every four hours. With the wider use of

"Much is being said of people coming from other shores here to sow the seeds of foreign ways of life, but much less is said of those who come here because they find in the fundamental principles of these United States the highest expression of their own hopes and aspirations. They

do not come to reform or to force upon it something which is foreign to it, but because they hope that, by making the fullest use of the opportunity which this country so lavishly offers to anyone prepared to grasp them, they may, in return, add their mite toward the structure of a culture and civilization, the like of which this earth has never seen. In fact, so fully do they appreciate the American institutions, that they often support them more wholeheartedly than do those whose fathers were born here, and who perhaps for that very reason do not appreciate their wonderful heritage as they should"—From the inaugural address of Dr. Julius Jensen, president of the St. Louis County Medical Society

Annual Meeting

May 6, 7, 8, and 9, 1940

New York City

THE banquet which coincides with the Annual Meeting of the Medical Society of the State of New York will be held at the Waldorf-Astoria on Tuesday evening, May 7, 1940. Among the speakers will be Chancellor Woodward Chase of New York University, and Dr. Alice Stone Woolley, president of the Women's Medical Society of New York State.

Music for the banquet and dance afterward will be furnished by the Doctors' Orchestral Society of New York under the supervision of its president and founder, Dr. Leopold Glushak.

Banquet tickets may be secured in advance from the New York Office, which, after April 15, 1940, will be at 292 Madison Avenue, New York City. The price of the tickets is \$5.00. Tables seating ten can be reserved.

The four days of the meeting begin with the House of Delegates on Monday, with the Scientific Sessions starting on Tuesday and carrying through Thursday. All three mornings and Wednesday afternoon will be devoted to the specialties, Tuesday and Thursday afternoons to the two General Sessions.

All members should register at the desk in the Silver Corridor. In past years a number have neglected to do this, and it is essential that the record be full and accurate. There is no charge for registration.

THE TREATMENT OF X-RAY BURNS AND OTHER SUPERFICIAL DISFIGUREMENTS

A. BENSON CANNON, M D, New York City

(Associate Professor of Dermatology, College of Physicians and Surgeons, Columbia University)

IN THIS paper I do not propose to make an exhaustive or scholarly survey of all the possible methods of treating acute and chronic x-ray burns and the other cutaneous disfigurements—keloids, acne rosacea, and scarring from acne—which I shall discuss here, nor do I make any claim to originality in the methods employed. I shall try, rather, to present a practical working plan for such treatments, based on methods which, from my experience, I have found to be most efficacious.

Chronic X-Ray Burns

Because of the increasing frequency with which we are consulted for the treatment of x-ray burns, particularly those of a chronic nature, and also because of the great danger that trophic ulcers or epitheliomas will develop on the site of the burn, consideration of the most practical and effective methods of removing such burns becomes a matter of first importance. Personally, I have obtained the most satisfactory therapeutic results in chronic x-ray burns by the use of desiccation with the electric needle, cauterization with trichloroacetic acid, scarification, or, sometimes, by a combination of all three methods.

I consider desiccation to be the most effective of all these methods, particularly when the burn covers a large area. My procedure is to wash the surface to be treated, first with warm water and soap, and then with a 70 per cent solution of alcohol. I then freeze the affected part with ethyl chloride and wipe it off quickly with cotton, in order to prevent the ethyl chloride from igniting. Then, using the lowest current possible with the desic-

cating needle, I lightly desiccate all of the dilated blood vessels and the elevated scars, and bevel off the edges of the depressed scars. When the entire area has been desiccated I wipe it off once more with cotton pledgets saturated with alcohol, and apply a calamine liniment containing 2 per cent of boric acid over the entire treated surface. I use a skin-colored liniment, which so effectually conceals the disfigurement that after it is applied the patient is able to leave the office looking little the worse for the treatment.

Desiccation requires a great deal of time, for it must be done slowly and painstakingly. Frequently, when the entire face, neck, and ears, or one extremity is involved, I have taken as much as three or four hours to complete the treatment. In case the disfigurement is so extensive that the desiccation is likely to be tiring or painful, or if the patient is very nervous, I find it well to give him 1½ grains of pentobarbital sodium and wait until he has become relaxed and drowsy from the effects of the drug before beginning the desiccation. Sometimes I give him, instead, an injection of codeine or morphine, the choice of preliminary anesthetic depending, of course, on the extent of the area to be treated, the degree of the disfigurement, and the nervousness of the individual patient.

I always instruct the patient to apply warm boric acid compresses to the treated parts for fifteen or twenty minutes three times a day, and to use calamine oil immediately afterward. At night he should apply a thick coating of cream made of equal parts of lanolin and eucern. He should be made to realize the importance

of keeping the parts well lubricated with oil or cream, not only immediately after the treatment, but for all the rest of his life, for such treatment helps to keep the tissues soft and thus acts as a preventive of keratoses and epitheliomas.

If the skin is very severely scarred from x-ray burns I often, at one sitting, paint the larger scars with trichloroacetic acid and the small, sieve-like, pitted ones with either trichloroacetic acid or a 10 per cent solution of phenol. If the area to be treated is very extensive, a more drastic method of cauterization is called for. In such cases I dip a wooden applicator into a 50 per cent solution of phenol, drag it across the scarred surface, and, as the skin whitens, neutralize the acid with a 70 per cent solution of alcohol. Usually by the end of a week the skin has recovered sufficiently from the effects of the treatment so that it can be cauterized a second time. As a rule, though, I think it is better to wait two weeks or even longer before repeating the cauterization.

If there are any epitheliomas present they should be removed at the same treatment session by means of a bipolar current run through a platinum loop, after which the base and edges of the wound should be curetted and desiccated, and then boric acid ointment dressings should be applied to the entire wounded area. Some dermatologists are of the opinion that it is impossible to prevent the development of epitheliomas in old x-ray burns and that all the patient can do is to have them removed as they appear. It has been my experience that desiccation, and sometimes also cauterization, of chronic x-ray burns not only brings about a tremendous improvement in the patient's appearance but also delays, and in some instances even helps to prevent the occurrence of epitheliomas.

I recall 1 young woman patient from whose face I had removed, annually for five years, anywhere from 1 to 4 epitheliomas which developed on the scarred surface of an old x-ray burn. The disfigurement was so great that the patient was very much handicapped in her efforts to find employment. I finally persuaded

her to allow me to try desiccation treatments. Her face improved to such an extent that she was soon able to secure a position as a model. Furthermore, in the ten years which have elapsed since she received the last desiccation treatment, she has had only 1 epithelioma. Five years ago I treated another patient for extensive x-ray burns and epitheliomas of the face. She had had several epitheliomas removed previously. I removed 6 epitheliomas from her face and desiccated the entire burned area at the first treatment, and the patient has been entirely free from epitheliomas since that time.

I could quote numerous other instances of patients who had suffered repeated occurrences of epitheliomas annually, or even oftener, whom I have treated by desiccation, with the result that they have not been troubled with epitheliomas for periods varying from two to four years after the last treatment. Hence, not only for its cosmetic effect, but also because it tends to prevent the development of epitheliomas, desiccation therapy of chronic x-ray burns is a decidedly advantageous method. True, it requires the expenditure of a great deal of time and the exercise of infinite patience on the part of the dermatologist, it is hard on his eyes, and it is physically exhausting. But the rewards, in terms of the patient's improved appearance, peace of mind, and comparative freedom from threats of future malignant disease are so great as to outweigh completely any personal inconvenience to the physician.

For localized x-ray burns, particularly those in accessible areas, I advocate surgical removal of the part, after which the flaps should be sutured together in such a manner as to secure as inconspicuous a scar as possible. Sometimes, too, skin grafts may be used. The advantages of surgical excision are threefold: (1) it gives a more pleasing cosmetic result than other methods, (2) it brings about a permanent cure, and (3) it practically insures the patient against the possibility of the tissues breaking down in the future.

FIG 1 X-ray burn involving side of face, and showing pigmentation scarring, and contraction. The distinct white, atrophic areas visible resulted from previous application of carbon dioxide snow. Treated by desiccation

FIG 2 Extensive x-ray burn, showing atrophy, scarring telangiectasis, and epithelioma. Treated by desiccation.

Acute X-Ray Burns

While we are not consulted so frequently for the treatment of acute x-ray burns, we do see them occasionally, and also trophic ulcers which have developed at sites where old x-ray scars have broken down. Complete amputation of the sloughing, burned area is the best method of treatment for such burns. Before removing the ulcer, however, one must first make sure that it has become localized, that it is free from infection, and that the surrounding swelling and vesiculation have entirely disappeared. After the scar has been amputated the flaps should be sutured together and skin grafted on to the wound.

If the acute burns are so extensive or their location is such that they do not lend themselves well to surgical removal, excellent results may be obtained by thoroughly desiccating and curetting the ulcerated area and then applying Aloe vera leaf. Although wounds of this type heal slowly, from six weeks to four months usually being required for complete

healing, they do invariably heal satisfactorily and completely, and leave few, if any, traces of the former burn. I often use Aloe vera leaf for such burns without doing any preliminary desiccating or curetting. The wound, however, heals almost twice as slowly as when it is desiccated and curetted before the leaf is applied. This method has the further disadvantage, also, that the residual scar is not always free from telangiectases.

Although Aloe vera leaf is by far the best treatment that I know of, except surgical therapy, for the treatment of painful, sloughing x-ray burns, it unfortunately sometimes produces a dermatitis, with redness, swelling, and, occasionally, vesiculation of the surrounding parts, accompanied by pain so severe as to require the administration of local or systemic opiates for its relief. Aspirin ointment (1 Gm. of powdered aspirin to 1 oz. of vaseline or cold cream) applied thickly over the painful part will also help to relieve the pain. If used for sev-

FIG 3 Generalized keloids following pustular syphilis in mulatto. Treated by painting lesions with trichloroacetic acid, followed by roentgen irradiation

eral days in succession this ointment will cause the skin to become puckered, grooved, and white in appearance, and in many ways to resemble skin which has been treated with strong salicylic acid. This is not a keratolytic effect, however. Orthoform ointment (10 gr per ounce) or orthoform powder sprinkled lightly over the wound will give immediate relief from pain, but unfortunately it cannot be used for more than a few days at a time, for it often produces a severe dermatitis with all its accompanying pain and discomfort. Neither hot nor cold wet dressings give much relief, and indeed, in many instances, they actually increase the pain.

Quite frequently we are consulted by patients who complain only of a dryness, roughening, and pigmentation of the skin. They give a history of having had

x-ray treatments for an old acne, usually several years previously, but they usually have not the slightest suspicion that the earlier x-ray treatments may have had anything to do with the present condition of their skin. The moment such a patient walks into the consultation room the dermatologist will be led to suspect that here is a victim of excessive radiation therapy, for the skin of his face, and particularly his nose, has a typical, slightly pinched, thinned appearance, and often a slight wrinkling on the chin and at the sides of the mouth is apparent when he smiles. Close inspection of the skin under a bright light, or, in very mild cases, under the lens, will reveal a definite thinning and dryness of the skin in some places, and sometimes a scaling and a moderate degree of wrinkling. In more pronounced cases pea-sized areas of macular pigment are visible. Quite frequently there will be evidences of telangiectasis or definite scarring.

For this type of case we usually depend on scarification, or, in the milder ones, on massage with keratolytic ointments containing salicylic acid either alone or in combination with betanaphthol. We remove the pigmented spots carefully by desiccation, and when the treatment is completed, apply calamine oil over the affected area. The patient is instructed to use this preparation frequently during the day, and a cream at night, in order to keep the tissues soft.

Keloids

I feel that success in the treatment of keloids depends in large measure on the stage in their development at which therapy is begun. If the keloid is treated in the early period of its growth, a cure is practically assured, but if it is allowed to develop, the keloidal mass frequently becomes so hard and resistant that no amount of x-ray therapy, even to the degree of a burn, will be of any avail. I have often heard the opinion expressed that keloids will disappear spontaneously. Instances of such disappearance are, I believe, comparatively rare. It has more often been my experience that

the trauma resulting from the patient's scratching of the burning, itching keloids served only to irritate them, and that, far from showing any tendency to disappear, the keloid more often than not was aggravated by lack of treatment. In any case, I would certainly never advocate postponing treatment just in order to see whether or not the keloid would eventually disappear of itself.

For early keloids I usually find that x-ray therapy alone is the best treatment. I ordinarily give 150 r unfiltered or 275 r filtered through 3 mm of aluminum ($1\frac{1}{2}$ erythema dose) at intervals of two weeks. I recall the case of a patient who, having fallen asleep while smoking, had sustained severe burns when the celluloid shade on her bedside lamp caught fire from her cigarette. The burned portion of the skin showed large, hypertrophic, shiny, red scars, frank keloids, and some areas of beginning contraction. We gave her three treatments, each consisting of 150 r unfiltered ($1\frac{1}{2}$ erythema dose) at two-week intervals. The results far exceeded my most optimistic expectations. While the skin still had a smooth, white, atrophic appearance, the scars were so much improved that when the patient used liquid powder and makeup they were scarcely visible, even at close range.

Another patient was referred to me several years ago by a New York hospital for the treatment of a keloid involving the skin over the entire abdomen. This patient had been severely burned when a nurse, in preparing her for an abdominal operation while she was under a general preliminary anesthetic, used nitric instead of chromic acid to paint the abdomen. When the wound healed some six weeks later a violently red, shiny keloid had formed, which was elevated about one-fourth inch above the surface of the skin. The patient complained that it itched and burned severely. We gave her 225 r unfiltered ($3\frac{1}{4}$ erythema dose) and prescribed a calamine lotion containing phenol. The patient did not return for several months. When I did see her, however, the skin over the entire abdomen was smooth and white. A slight

amount of atrophy and some enlargement of the follicles were the only evidences of the previously existing keloids.

Hard or organized keloids of long standing will require such large doses of x-ray to bring about their complete involution—if it can be done at all—that I think it is better to give only one or two radiation treatments and then desiccate the keloid or cauterize it with trichloroacetic acid or acid nitrate of mercury. Care should be taken when desiccating it to stay well within the margin of the keloid. The patient is instructed to apply dressings of boric acid ointment daily. This procedure has the advantage of requiring comparatively little x-ray therapy. We try never to use more than 750–1,500 r unfiltered or 1,375–2,750 r filtered through 3 mm of aluminum ($2\frac{1}{2}$ –5 erythema doses) in any case.

If the keloidal area is not too extensive and is located in a place suitable for excision, I advocate surgical removal, preceded and usually followed by radiation therapy. By this method one can obtain excellent cosmetic results in a comparatively short time.

I have found the removal of keloids from within the scars of old x-ray burns to be an exceedingly difficult problem. As a rule I rely on the desiccating needle in treating such cases, taking care, as usual, to stay well within the margin of the keloid, or I have frozen the keloid with ethyl chloride and then, using a scalpel, have excised it level with the skin and desiccated the base. If one is careful always to burn down any superfluous granulation with acid or to curet it as quickly as it forms, one can usually cure all the keloids existing in the scars and prevent the formation of others.

Acne Rosacea

One of the most brilliant cures that I know of in acne rosacea is obtained by scarification. I speak here, of course, of those cases of acne rosacea in which one is unable to find any focus of infection which might account for the condition, or in which the usual dietary measures, hydrochloric acid taken internally, the use of

FIG 4 Acne rosacea Cured by scarification

astringents and other types of local applications, and radiation therapy, have all proved equally unavailing

One complete scarification of all the parts affected will usually produce amazingly beneficial results within one week or ten days. While the operation is a most bloody one, patients are often surprised at the very slight amount of pain which it causes them. Usually they complain more of the nervousness which thoughts of the operation arouse in them than of any actual pain which it may cause. For this operation I have two abscess knives, which I never use for any other purpose, the blades of which are always kept as sharp as the edge of a razor. The patient is put in a reclining position on the operating table, his face carefully cleansed with cotton pledgets saturated in alcohol and then dried thoroughly. Next, starting from the bottom of the affected area and working up, I make multiple, parallel, superficial incisions about one thirty-second of an inch apart, horizontally across the entire reddened surface, taking care never to go below the epidermis. I place pledgets of

FIG 5 Acne vulgaris, showing scarring, which was healed by scarification, and also by ringing margins of deeper pits with trichloroacetic acid

cotton over the bleeding areas as each incision is made, and watch carefully to see that no blood gets on the untreated surfaces or obscures the skin. When the surface to be treated has been entirely covered with the horizontal incisions, I go over it again and make vertical incisions in the same manner, so that the reddened area has a checkered appearance. Within about ten minutes after the last incision is made the bleeding will have practically stopped and one can remove the cotton pledgets. The face should then be covered with a calamine lotion containing boric acid and a great deal of oil. We find it a good idea to give the patient pledgets of cotton or gauze to take with him when he leaves the office, so that he can wipe away any serum which may ooze. Anywhere from one to four or five scarifications will usually suffice to clear up even the most aggravated cases of acne rosacea without leaving any scars or other evidences of the treatment undergone.

Scarring from Acne

Acne scars constitute one of the most common defects of the skin which dermatologists are called upon to treat. Not infrequently one finds that patients requiring such treatment still have a few acne lesions scattered here and there be-

tween the scars, which should be removed before the scars are treated. The first step in this procedure is to express the pus from the pustules. To do this I sharpen a needle-point stick, dip it into phenol, and then, while holding the pustule between the thumb and index finger, bore the point of the stick into the pustule. All comedones are carefully removed. The pitted scars are then scarified by the same method as that described for the treatment of acne rosacea. I always try to avoid scarifying the bases of the scars, and, if the scars are close together, I make the incisions only on their rims and on the intervening tissue. After the scarification is completed I cover the treated areas with calamine oil or liniment, and the patient is allowed to leave the office. He is instructed to apply warm compresses for twelve or fifteen minutes, two or three times a day, and to apply calamine lotion in between the times when he uses the warm compresses. He should also spread cream thickly over the area at night. The treatment may be repeated, if necessary, within a week or ten days.

In treating large, deep scars resulting from acne, I "ring" the margins of the scars with trichloroacetic acid and try to bevel off the edges so that they will blend in with the surrounding skin. When the beveling process has been accomplished I scarify the area in order to lessen the disfigurement still further.

Sometimes one finds multiple, closely studded and pitted scars which the patient will usually refer to as "enlarged pores" or "pits." These we treat by dragging a wooden applicator dipped in phenol solution over the surface of the skin and, as the skin becomes white, neutralizing the phenol with a 70 per cent solution of alcohol. Occasionally I treat these scars by inducing a severe keratolysis by means of blistering doses of Alpine light, or by applying either a 10 or 15 per cent solution of salicylic acid or a preparation containing both strong salicylic acid and betanaphthol. None of these last-mentioned methods will remove the scars entirely, but they will

help to flatten an elevated scar, and sometimes they will produce such extensive peeling that the scarring will be appreciably lessened and the appearance of the skin will be greatly improved.

Summary

Excision of x-ray burns is the treatment which will give the best results. Where extensive areas of the skin have been affected by excessive radiation one can greatly improve the appearance of the skin and minimize the probability of cancer in the affected tissues by removing the dilated blood vessels, elevated scars, and keratoses with the electric needle, sometimes in conjunction with the application of trichloroacetic acid to the scars.

Early therapy of keloids is of great importance for successful cure. X-ray therapy offers the most satisfactory results.

Scarification for acne rosacea and for scarring following acne often gives the most beneficial results.

Discussion

Dr Earl L. Eaton, *Buffalo, New York*—I am very grateful to have the opportunity of being present and of listening to this very interesting and instructive paper on the "Treatment of X-ray Burns and Other Superficial Disfigurements." Dr Cannon has covered the subject very thoroughly so that it leaves very little for me to add to what has already been said.

The treatment of roentgen-ray burns is, of course, very important to all of us. From my own experience, I think we are fortunate in seeing less of these burns in the past few years than we did previous to this time and I feel that this is due to the fact that we have better methods of measuring accurately the total dosage. We know that the total dosage should not exceed about three skin units in any one area. Furthermore we know the disastrous and damaging effects of roentgen ray and radium ray on normal tissue. We know that in many cases, particularly of skin disease, if definite improvement or cure has not taken place after six to eight treatments it is not wise to continue indefinitely to treat with roentgen ray, first because the lesion or lesions treated do not react to the therapy, and second, damage may be done through continued use of the agent.

FIG 4 Acne rosacea Cured by scarification

astringents and other types of local applications, and radiation therapy, have all proved equally unavailing

One complete scarification of all the parts affected will usually produce amazingly beneficial results within one week or ten days. While the operation is a most bloody one, patients are often surprised at the very slight amount of pain which it causes them. Usually they complain more of the nervousness which thoughts of the operation arouse in them than of any actual pain which it may cause. For this operation I have two abscess knives, which I never use for any other purpose, the blades of which are always kept as sharp as the edge of a razor. The patient is put in a reclining position on the operating table, his face carefully cleansed with cotton pledgets saturated in alcohol and then dried thoroughly. Next, starting from the bottom of the affected area and working up, I make multiple, parallel, superficial incisions about one thirty-second of an inch apart, horizontally across the entire reddened surface, taking care never to go below the epidermis. I place pledgets of

FIG 5 Acne vulgaris, showing scarring, which was healed by scarification, and also by ringing margins of deeper pits with trichloroacetic acid

cotton over the bleeding areas as each incision is made, and watch carefully to see that no blood gets on the untreated surfaces or obscures the skin. When the surface to be treated has been entirely covered with the horizontal incisions, I go over it again and make vertical incisions in the same manner, so that the reddened area has a checkered appearance. Within about ten minutes after the last incision is made the bleeding will have practically stopped and one can remove the cotton pledgets. The face should then be covered with a calamine lotion containing boric acid and a great deal of oil. We find it a good idea to give the patient pledgets of cotton or gauze to take with him when he leaves the office, so that he can wipe away any serum which may ooze. Anywhere from one to four or five scarifications will usually suffice to clear up even the most aggravated cases of acne rosacea without leaving any scars or other evidences of the treatment undergone.

Scarring from Acne

Acne scars constitute one of the most common defects of the skin which dermatologists are called upon to treat. Not infrequently one finds that patients requiring such treatment still have a few acne lesions scattered here and there be-

tween the scars, which should be removed before the scars are treated. The first step in this procedure is to express the pus from the pustules. To do this I sharpen a needle-point stick, dip it into phenol, and then, while holding the pustule between the thumb and index finger, bore the point of the stick into the pustule. All comedones are carefully removed. The pitted scars are then scarified by the same method as that described for the treatment of acne rosacea. I always try to avoid scarifying the bases of the scars, and, if the scars are close together, I make the incisions only on their rims and on the intervening tissue. After the scarification is completed I cover the treated areas with calamine oil or liniment, and the patient is allowed to leave the office. He is instructed to apply warm compresses for twelve or fifteen minutes, two or three times a day, and to apply calamine lotion in between the times when he uses the warm compresses. He should also spread cream thickly over the area at night. The treatment may be repeated, if necessary, within a week or ten days.

In treating large, deep scars resulting from acne, I "ring" the margins of the scars with trichloroacetic acid and try to bevel off the edges so that they will blend in with the surrounding skin. When the beveling process has been accomplished I scarify the area in order to lessen the disfigurement still further.

Sometimes one finds multiple, closely studded and pitted scars which the patient will usually refer to as "enlarged pores" or "pits." These we treat by dragging a wooden applicator dipped in phenol solution over the surface of the skin and, as the skin becomes white, neutralizing the phenol with a 70 per cent solution of alcohol. Occasionally I treat these scars by inducing a severe keratolysis by means of blistering doses of Alpine light, or by applying either a 10 or 15 per cent solution of salicylic acid or a preparation containing both strong salicylic acid and betanaphthol. None of these last-mentioned methods will remove the scars entirely, but they will

help to flatten an elevated scar, and sometimes they will produce such extensive peeling that the scarring will be appreciably lessened and the appearance of the skin will be greatly improved.

Summary

Excision of x-ray burns is the treatment which will give the best results. Where extensive areas of the skin have been affected by excessive radiation one can greatly improve the appearance of the skin and minimize the probability of cancer in the affected tissues by removing the dilated blood vessels, elevated scars, and keratoses with the electric needle, sometimes in conjunction with the application of trichloroacetic acid to the scars.

Early therapy of keloids is of great importance for successful cure. X-ray therapy offers the most satisfactory results.

Scarification for acne rosacea and for scarring following acne often gives the most beneficial results.

Discussion

Dr Earl L. Eaton, *Buffalo, New York*—I am very grateful to have the opportunity of being present and of listening to this very interesting and instructive paper on the "Treatment of X-ray Burns and Other Superficial Disfigurements." Dr Cannon has covered the subject very thoroughly so that it leaves very little for me to add to what has already been said.

The treatment of roentgen-ray burns is, of course, very important to all of us. From my own experience, I think we are fortunate in seeing less of these burns in the past few years than we did previous to this time and I feel that this is due to the fact that we have better methods of measuring accurately the total dosage. We know that the total dosage should not exceed about three skin units in any one area. Furthermore, we know the disastrous and damaging effects of roentgen ray and radium ray on normal tissue. We know that in many cases, particularly of skin disease, if definite improvement or cure has not taken place after six to eight treatments it is not wise to continue indefinitely to treat with roentgen ray. First, because the lesion or lesions treated do not react to the therapy and second much damage may be done through continued use of the agent.

It is possible that we may see an increase in the incidence of roentgen-ray burns because of the high-voltage machines now being used in the treatment of malignancy.

Carl Zeiler and Carl Hoede of the University of Würzburg observed that the skin tolerance dose has been largely overestimated. They are of the opinion that our present skin unit dose is one-quarter or one-third too high and that late damages may appear if these doses are given two or three times in one year. They also state that roentgen and radium rays act on the chromatin, disturbing the normal mitosis, this effect being permanent and leading to diminished metabolic function of the cells over the irradiated areas. In lesser degrees of cell damage, degenerative cell types may develop, occasionally producing carcinoma. They state that following roentgen-ray irradiation, we find changes in the nuclei and in the mitotic figures of the cells of the skin, subcutaneous tissue, and small blood vessels. As time goes on, these changes may disappear superficially but may be demonstrated as late as two years following one x-ray exposure, then will be demonstrated by decrease in defensive powers of irradiated areas. They also tell us that a skin that has been irradiated should have protection against constant rubbing of clothing, overexposure to ultraviolet light, or the application of different irritating medicines such as tar, iodine solutions, etc. The general condition of the patient should be watched especially in cases of cardiac insufficiency, diabetes, malaria, hypertension, chronic kidney disease, tuberculosis, etc.

In the treatment of radiodermatitis we cannot prevent a reaction, as far as is known, once the exposure has been given. In the acute radiodermatitis, mild ointments may be applied, olive oil or mineral oil, ice-cold compresses to relieve pain, wet dressings of olive oil or witch hazel can be used. In second-degree radiodermatitis, the same mild ointments and mild applications should be used, such as a 1-20 liquor aluminum acetate solution, soothing lotions such as calamine lotion or calamine liniment, as suggested by Pusey. For third-degree reactions, in the beginning, soothing local applications can be used. It may be necessary because of pain to use anesthesia, or internal administration of codeine or morphine. Surgical procedure may be necessary for removal of necrotic tissue.

In chronic radiodermatitis, treatment depends on what is found to be present. In my own experience, where telangiectases and keratosis have formed, I have used electrodesiccation that is the monopolar desiccating current. For those lesions that are wrinkled, atrophic, and dry, I

use bland emollient ointments and protect them from irritation as much as possible.

European specialists report favorable results in the treatment of ulcers (with no evidence of malignant degeneration) with ointments impregnated with radium salts or radium emanation. My experience in the use of these agents has been very limited but, from a survey of the literature, it appears that the benefits derived from the use of these ointments have been greatly overestimated. Dr. Miescher of the Zurich Clinic, who has had a large amount of experience with this type of preparation, recently stated that he had abandoned these remedies and has employed other palliative or surgical measures.

My own personal experience in ulcers, both malignant and nonmalignant, has been electrodesiccation or surgical procedure—removal of ulcer and closing of the wound with sutures, grafts, or flaps, depending on the feasibility in the particular case. I have found that this gives the most satisfactory end result and is much less disturbing and painful to the patient. The plant, *Aloe vera*, has been used in the treatment of radiation ulcers but I have had very little experience with it, using it in only 1 case and failing to secure any marked results. However, the literature discloses cases that have shown marked improvement by the use of this leaf.

Keloids—In the young, growing, erythematous keloid, the use of the x-ray is generally satisfactory in suberythematous doses and, in most mild cases, filtered. As the lesion becomes older, less vascular, and harder to the touch or on palpation, it is more radioresistant and the result of treatment not nearly so good. Unless the lesion is very small or on an area of the body where an extremely good cosmetic result is not so important, I sometimes use suberythematous doses of x-ray for a few times and improvement can be noted, however, for complete removal in these old cases I feel that surgery should be resorted to and the wound closed with as few sutures or clips as possible, then watched very carefully for any formation of new keloid tissue. Of course, at the first sign of return, treatment should be started. In my own practice, I have gone a step further in these cases and given a couple, sometimes three suberythematous doses, starting my first treatment as soon as the wound is healed, thus preventing any return of the former keloid.

Acne—As for treatment of scars from acne, we might first say that certain types of acne may be excluded from x-ray therapy—those mild cases where local and constitutional remedies and hygienic measures should be tried first, the acute, inflamed eruptions should be allowed to

subside before therapy is started, x-ray should not be employed in infantile acne, in certain toxic cases roentgen therapy should be deferred until the toxin is eliminated

We very often have scarring following the treatment of acne and we all are familiar with the pitlike scars that are present in these cases as a result of the disease. There is a divergence of opinion as to whether or not one should remove the comedones and evacuate the pustules before treating the patient with x-ray. It has been my method to do this and I feel that my results have been better as far as the disease itself and the improved cosmetic results are concerned

Where scarring is present after a course of x-ray treatments have been given, I have found that exposures to ultraviolet light have caused marked improvement and even disappearance of the scars. Andrews states that in most cases ultraviolet light energy is specific for these sequelae of acne. The best results are obtained by giving erythematous or even blistering exposures of ultraviolet light energy in these cases

Dr Howard Fox, *New York City*—In regard to the ill effects of roentgen-ray treatment, I am glad to say that few of them at the present time are caused by dermatologists. We have learned how to standardize the dosage and to keep it within safe limits. I agree with the speaker that small areas of damage due to x-rays are best treated by excision. I also agree that treatment by solid carbon dioxide, even with the mildest application is unsatisfactory as it produces disfiguring white patches

We all agree, I think, that keloids are best treated with x-rays or radium with or without surgical excision. Furthermore, such treatments are only satisfactory when the lesions are comparatively recent. When they have existed a year or two, the outlook for a favorable result is poor. Keloids can be destroyed by electrodesiccation and then irradiated. The resulting scar, from a cosmetic standpoint, is less favorable than when the lesion is excised. It seems impossible, however, to excise a keloid and leave a narrow linear scar. Invariably, in my experi-

ence, such scars have widened to a broad band even though irradiation has prevented their further elevation

I agree entirely with Dr Cannon about the value of scarification in acne rosacea but I have usually found it difficult to persuade my patients to submit to this method of treatment

Dr Timothy J Riordan, *New York City*—A word or two about the histopathology of keloids deserves mention. In lesions of short duration young fibroblasts are found which are radio-sensitive. In lesions of long duration old connective tissue cells which are radioresistant are found along with hyaline degeneration of the collagen. The latter is necrotic tissue. I believe these points serve to explain the improvement achieved with roentgen therapy in early lesions and failure in older lesions

Dr A. Benson Cannon, *New York City*—With regard to the use of electrolysis in x-ray burns, I feel that it is too tedious and time-consuming, and that it too often causes pitting scars. One can accomplish the same results almost ten times more quickly by desiccation than by electrolysis. In addition, desiccation presents the advantage that the skin does not have to be touched with the desiccating needle, whereas in electrolysis the skin is punctured and a scar is likely to result

I did not mean to convey the impression that it was an easy matter to remove keloids by surgery combined with pre- or postoperative irradiation. On the contrary, to secure satisfactory results by this method it is often necessary to persist in the treatments for quite a long period, and occasionally the mode of treatment has to be changed before the condition shows any signs of improvement.

I also use both Alpine and Kromayer light to treat scarring from acne, giving doses massive enough to cause blistering and subsequent exfoliation. I think this is an excellent method, since it peels off the epidermis and helps to clear up any acne which may still remain. Its one disadvantage is that it burns not only the margins but the bases of the scars as well

A GUESS AT THE NUMBER ONE PRESCRIPTION

What drug or what substance is it that a doctor prescribes oftenest? An interesting subject for speculation. If we should finally determine that this reagent was possibly digitalis or aspirin, it would be reasonable to suppose that the doctors who so frequently prescribe these remedial agents would be greatly interested in the purity of the composition, the manner of the assay, and the methods by which they were made available

to the profession and to the public. Without attempting to cite statistics in the matter, the editor of the *Journal of the Indiana State Medical Association* believes that it is not digitalis or any other drug in the usual sense of the word that is prescribed most often, but that probably *milk* is mentioned oftener by the doctor than any other remedial agent with possibly water and certain foods in second and third places

CHRONIC PYELONEPHRITIS—A CAUSE OF HYPERTENSION AND RENAL INSUFFICIENCY

WILLIAM S McCANN, M D , Rochester, New York

(From the Department of Medicine, University of Rochester School of Medicine and Dentistry, and the Medical Clinic of the Strong Memorial and Rochester Municipal hospitals)

IN RECENT years it has become increasingly evident that certain infections of the urinary tract, which were formerly thought of as relatively trivial attacks of cystitis or "pyelitis" are, on the contrary, of the greatest seriousness and importance. Wilson and Schloss¹ some years ago pointed out that the so-called "acute pyelitis" of infants was, in fact, a pyelonephritis. More recently Longcope² has described a chronic form of bilateral pyelonephritis, occurring without any obstructive lesions in the urinary tract, progressing insidiously over a long time to a state of renal insufficiency, and frequently characterized by hypertension. The individual episodes of urinary infection may, of themselves, appear trivial, so that an appreciation of their significance has come in retrospect after the damage has been done. At the same time Peters³ has called attention to the probability that antecedent urinary infections play an important etiologic role in the late "toxemias" of pregnancy, which are characterized by hypertension.

The work of Goldblatt,⁴ who produced hypertension experimentally by partial renal ischemia, has led to the discovery that a pressor substance is produced within the kidney, which acts through a humoral mechanism, and which may be formed if unilateral renal ischemia is induced. This same pressor substance is probably responsible for the hypertension of pyelonephritis, since Butler⁵ has reported the relief of hypertension by nephrectomy in 2 cases of unilateral pyelonephritis in children. The pressor substance is also produced apparently by urinary obstruction, since hypertension

is commonly associated with hydronephrosis, and extracts prepared from hydronephrotic kidneys by Williams and Harrison⁶ were found to yield greater pressor effects than those obtained from normal kidneys.

Case Reports

Case 1—D Y, a young married woman aged 33, was admitted to the Strong Memorial Hospital in August, 1937, with marked hypertension, hypertensive retinopathy, cardiac hypertrophy, albuminuria, bacilluria, and many leukocytes in the urinary sediment. Renal function was seriously impaired, the urea clearance was 25 per cent of normal, and at times the nonprotein nitrogen of the blood was elevated, 44–67 mg / 100 cc. She was moderately anemic. Blood pressure 230/140.

The history was that on her honeymoon eleven years previously she had suffered from a "deflorescence pyelitis," which had lasted for several weeks, ultimately responding to medical treatment. The first two pregnancies had terminated in miscarriages. In each of the next three pregnancies which went to term, there were severe late "toxic" manifestations. The blood pressure was elevated and there was edema but no eclampsia. The last child was born five years before admission. For two and one-half years she had been under the care of a physician for hypertension.

In the hospital the patient was treated by transfusion, then with mandelic acid, and later with sulfanilamide, in the hope of clearing the urinary infection with *B. coli*. These measures were effective at first. Treatment was continued in the urologic clinic by Dr. W. W. Scott. While the patient's condition remained fairly satisfactory, bacilluria and pyuria kept recurring.

Fig. 1 shows the retrograde pyelogram made in August 1937. The ureters were dilated though free at their orifices. The pelvis and calyces were distorted, and the renal shadows

Read at the Annual Meeting of the Medical Society of the State of New York, Syracuse, April 26, 1939

FIG 1 Unilateral pyelogram in Case 1, showing hydroureter and the extreme distortion of the calyces and pelvis

were very small. In view of the reduced renal function pyelograms were made on one side at a time.

An Addis urinary sediment count made August 8, 1937, was as follows: twelve-hour night specimen 800 cc, sp gr 1.011, reaction slightly alkaline, rbc 10,200,000, leukocytes 176,400,000, total protein 150 mg per cent.

In January, 1938, the patient suffered from a geniculate ganglion herpes with facial paralysis on the left side.

In May, 1938, she was re-admitted to the hospital for study, on account of severe headaches and mild uremic symptoms (N.P.N. of blood 75 mg/100 cc.)

In July, 1938, cardiac symptoms began with dyspnea on effort, and later severe nocturnal attacks of cardiac asthma. Nausea and vomiting became frequent. The blood pressure was 240/160. The hemoglobin was 9 Gm./100 cc. of blood and rbc 2,600,000. Blood nonprotein nitrogen had risen to 100 mg/100 cc. Some improvement followed the use of digitalis and treatment of the anemia.

In August 1938, it was discovered that the patient was pregnant through the fact that she had an incomplete abortion, following which a curettage was done, and the patient again showed some temporary improvement. On August 27, 1938 she was again admitted in uremia and

FIG 2 Kidneys and urinary tract of Case 1, to show extreme degree of contraction of kidneys

failed progressively to the time of her death, one month later.

At autopsy the kidneys were found to be markedly contracted and the ureters greatly dilated. No obstruction of the ureters was found. The gross appearance of the kidneys and urinary tract is seen in Fig 2. The microscopic changes are shown in Fig 3. In this section one can see the evidence of chronic interstitial inflammation. Many tubules are dilated in such a way as to suggest the appearance of thyroid, a feature which has been re-

FIG 3 Microscopic appearance of kidney in Case 2, showing interstitial inflammatory reaction, dilated tubules, irregular glomerular changes, and arteriosclerosis

marked upon by other observers. Irregular glomerular lesions were observed. There was considerable arteriosclerosis.

Case 2—E W, a young unmarried woman aged 25, was admitted to the Strong Memorial Hospital because of severe headaches, visual disturbances, nausea, and vomiting. The history records attacks of urinary infection from the age of 1 year. Since the age of 12, which she can remember clearly, these attacks have occurred at intervals of about six weeks. They consisted of fever, burning and frequency of urination, pain in the lumbar region, headaches, nausea, and vomiting. The acute phase of the attack was usually of four to five days' duration followed by a period of convalescence lasting five to six days. The precipitating factor was usually some strenuous physical activity.

On admission in March, 1939 she was found to have a marked hypertension, with systolic pressures ranging from 160 to 190 and diastolic from 110 to 130. The retinas show evidence of hypertensive change with papilledema and hemorrhages. The heart showed hypertrophy.

The urine sediment showed the following count of formed elements: leukocytes and epithelial cells 2,767,500, rbc 300,000, casts 136,000, twelve-hour night specimen was 615 cc, sp gr 1.014, and total protein content 300 mg/100 cc. The maximal urea clearance was 22 and 25 per cent of normal on two successive hours, and the creatinine clearance 31 cc/min. The phenolsulfonephthalein test showed an excretion of 22 per cent in two hours. Culture of the urine yielded a growth of nonhemolytic streptococci. Blood nonprotein nitrogen was 53, creatinine 3.2, proteins and chlorides normal.

This patient had first been studied in the hospital in 1932 at the age of 17. At that time the urea clearance test was 60 per cent of normal, and the phthalein excretion 55 per cent in two hours. Blood pressure was then 108/68. The urine at that time yielded *B. coli communis* on culture, showed a trace of albumin, and there were seen 6-8 leukocytes per hpf in an uncentrifuged specimen.

Cystoscopy was performed at that time by Dr. W. W. Scott, who noted inflammation and congestion in the region about the trigone and vesical orifice. No obstruction of the ureters was found. Pyelograms were not entirely satisfactory, but no evidence of hydronephrosis was obtained, and the pelves appeared to be somewhat distorted.

The patient was followed at frequent intervals in the urologic clinic from 1932 to 1939. At various times *B. coli communis* was isolated on culture, but on one occasion the urine yielded *Staphylococcus albus* in abundance, and on another a nonhemolytic streptococcus. Various agents were employed for combating the urinary infection: mandelic acid, hexamethylene amine and ammonium chloride, high acid ash diet, sulfanilamide, and during the period of staphylococcal infection neocarsphenamine was used. In each instance the clearing of the urine was temporary, no means having been found to prevent recurring attacks.

In February, 1938, the first note of elevation of blood pressure was made. At that time it was recorded as 150/90. The heart was only slightly enlarged. The phthalein excretion in two hours was 42 per cent. The urine, at the time, was free from pus or albumin.

In the period from February, 1938, to March, 1939, the hypertensive phenomena increased markedly, renal function diminished, and mild uremic symptoms occurred. In spite of warnings as to danger of pregnancy the patient married.

Case 3—A. A., a married woman aged 37, was admitted to the Strong Memorial Hospi-

tal November 4, 1936, and died December 21, 1936. On entry she was found to have pronounced hypertension 210/118, severe anemia, cardiac enlargement, gallop rhythm, congestion of the lung bases, and moderate edema. The electrocardiogram showed left axis deviation and changes indicative of myocardial damage. The urine was of low specific gravity, alkaline, showed a trace of albumin, no sugar. The sediment showed large numbers of leukocytes and both bacilli and cocci in pairs and chains. The degree of uremia was shown by the finding of marked elevation of the nonprotein nitrogen 162 mg, urea 126 mg, creatinine 19 mg/100 cc. Phthalein excretion was negligible. The patient complained of colicky pain in the left flank, radiating toward the pubis.

On cystoscopic examination, performed by Dr Jarman, the bladder showed marked evidence of infection, with edema in the trigone and about the ureteral orifices. No obstruction was encountered on the right side. On catheterizing the left kidney no drainage occurred. A pyelogram of the left kidney was obtained which is shown in Fig 4, indicating the presence of a hydronephrosis and hydroureter with obstruction near the ureterovesical junction.

Culture of the bladder urine yielded a growth of a nonhemolytic streptococcus.

Efforts at treatment failed and the patient died on December 21, 1936. Autopsy revealed a chronic pyelonephritis and pyonephrosis.

From the history the urinary infection began twenty years before the terminal illness, having occurred following a railroad accident in which she suffered compound fractures of both legs. Two years later she had a normal pregnancy, with no signs of "toxemia."

The duration of the elevated blood pressure may be inferred from the fact that she was in hospital with severe "asthma" nine years before her death, and the story from then on was one of repeated attacks of asthma and evidence of urinary infection. Five months before her death she had an attack of pneumonia and the uremic symptoms developed with increasing severity following this illness.

Case 4—H D., a married woman aged 29 was admitted to the Strong Memorial Hospital in November 1934, acutely ill, with pain in the epigastrium and vomiting. She was thought at first to have an acute cholecystitis, but later the finding of marked costovertebral tenderness, with pus and blood in the urine, elevation of blood pressure 165/110, retinal exudates, and edema of the disks, pointed toward an acute pyelonephritis. Culture of the urine yielded a growth of bacillus aerogenes. The nonprotein

FIG 4. Unilateral pyelogram of Case 3, showing hydronephrosis and hydroureter with obstruction near the ureterovesical junction.

nitrogen of the blood was 66 mg per cent. The urea clearance was 10 per cent of normal. There was leukocytosis and moderate anemia. After symptomatic treatment the patient went home without having had urologic study.

She was re-admitted one month later with pronounced hypertension, B P 220/135. The blood nonprotein nitrogen was 87 mg per cent. The patient was transferred to the Monroe County Hospital, where she remained for some months. She was re-admitted to the Strong Memorial Hospital a third time nine months after the second admission, this time in coma. Spinal puncture yielded bloody fluid. The blood pressure was greatly elevated, the non-protein nitrogen was 189 mg per cent. Death occurred shortly. An autopsy revealed acute and chronic pyelonephritis, cerebral hemorrhage, organizing pneumonia, pulmonary edema and congestion, cardiac hypertrophy, acute endocarditis of mitral and aortic valves, chronic cholecystitis, chronic pancreatitis, fat necrosis, healed.

The history is rather vague as to the exact onset of the trouble. The first urinary infection was said to have occurred following an abortion, date not given. In 1930, four years before her death, she was pregnant and was found to have hypertension and kidney trouble. She was under treatment following the birth of her child in the urologic clinic of another hospital.

The 4 cases briefly described above are typical examples of a common type of chronic recurring infection of the urinary tract, which may terminate in renal insufficiency and hypertension. The isolated episodes of urinary infection are apt not to be regarded seriously when the patient is seen in the early stages of the malady, and the tendency has been to consider them as infections of the urinary passages rather than of the kidneys themselves. Now that it is more clearly understood that they represent a slowly developing chronic interstitial nephritis, there can no longer be any excuse for failure to make a vigorous attempt to terminate the infection and to bring the process to a halt if possible.

Case 2 illustrates the fact to which Peters³ has called attention, that women who have had such urinary infections may suffer from the hypertensive phenomena of late pregnancy, which we speak of as "toxemias." In such cases the infectious process may have been quite latent or inactive until pregnancy occurred. Then one may witness either an exacerbation of pyelitis, or simply albuminuria, edema, and hypertension, and sometimes eclampsia. The exact reason why this occurs cannot be stated with certainty. It is possible that the "physiologic hydronephrosis" which begins early in pregnancy may cause the formation of the renal pressor substance of which mention has been made, and it is not unlikely that this substance is formed in greater amounts in kidneys which have been the seat of a pyelonephritis. If this proves to be true, then one may expect to find hypertension developing in nonpregnant women who have had "pyelitis" if subsequently some form of urinary obstruction occurs. The case abstract which follows bears upon this point.

Case 5—S H., a married woman aged 57, was seen in consultation January 11, 1939. She complained of shortness of breath and retro-manubrial pain on effort. The chief findings on examination were marked hypertension, B P 200/100, retinal arteriosclerosis of the hypertensive type, enlargement of the heart, systolic bruits at the mitral and at the aortic areas, the

latter being rough and faintly heard in the right carotid artery, and electrocardiographic evidence of left axis deviation, depression of the ST segments in leads I and II, and elevation in lead III.

The urine was found to be free from albumin or sugar, it was clear, slightly alkaline, of low specific gravity. The sediment did not reveal any excess of formed elements. The kidneys were not palpable, and there was no costovertebral tenderness. The history recorded the fact that the patient had suffered from a severe "pyelitis" 13 years before, and that she had been treated after cystoscopy by a urologist. Occasionally she had slight recurrence of frequency and burning of urination, but she regarded these as trivial.

On the basis of this history it was decided to have a cystoscopy performed by Dr W W Scott, and this was done. The urethra was found to be the seat of a stricture, the bladder was found to be hypertrophied and trabeculated. Retrograde pyelograms were made. These did not reveal appreciable hydronephrosis. However, the urethra was dilated, and the patient returned to the care of her family physician.

Reports from her physician show that her blood pressure has been much lower, the highest pressure recorded being 160/90 during the three-month period following this dilatation. The cardiac symptoms were greatly relieved by the lowering of the blood pressure.

This case is complicated by one fact. The pyelograms showed a dense shadow of irregular outline just above the left kidney, which was somewhat displaced downward. This was regarded as a tumor of the adrenal. The patient refused to have the mass explored surgically. The fact remains, however, that the fall in blood pressure followed the urethral dilatation.

Following this experience it was decided to carry out urologic studies, whenever possible, of patients with the so-called essential hypertension, that is, hypertension occurring in patients with normal urine and with good renal function.

Case 6—H C., a married woman aged 51, was admitted to the hospital in an attack of hypertensive encephalopathy on March 14, 1939. The patient had been under the care of a physician in Dayton, Ohio, for several years for high blood pressure. While visiting in Rochester she suffered severe headaches and on the day of admission had fallen unconscious while in the bathroom. She was conscious on admission.

FIG 5 Retrograde pyelograms of Case 6, showing bilateral hydronephrosis and ptosis of kidneys

Her blood pressure was 200/120. She was lethargic, speech was thick, tongue protruded slightly to the right, the neck was slightly stiff. Apart from this there were no striking neurologic abnormalities. The retinas did not show marked evidence of hypertensive changes and the disks were normal. The heart was somewhat enlarged. There was no orthopnea, no pulmonary congestion. There was slight pretibial edema.

The urine was slightly turbid, acid, sp gr 1.030, albumin trace, sugar none, and the sediment showed both granular and hyaline casts, 1-2 leukocytes per h p f, and no red cells. The nonprotein nitrogen was 33 mg. The CO_2 combining power was normal. The urine was sterile on culture.

On March 16 the patient was better. The blood pressure had fallen to 140/95. The phthalein excretion was 35 per cent the first half hour and 15 per cent the second.

The patient had a history of urinary infection fifteen years before. This was characterized by heavy albuminuria, edema, and foul-smelling turbid urine, the attack lasting for five weeks. Since then there have been frequent episodes of burning and frequency of urination. In 1934 her blood pressure was 160/90.

In view of this history a cystoscopic examination was made by Dr W W Scott. This revealed polyps at the vesical neck. The urine

FIG 6 Pyelograms of Case 7, malignant hypertension, showing bilateral hydronephrosis due to urethral stricture and ptosis of kidneys

from both sides was normal and the function good. The retrograde pyelograms showed ptosis of both kidneys and a moderate degree of hydronephrosis (Fig 5).

Following this procedure the patient's condition was improved, at least temporarily, but sufficient time has not elapsed to determine the full extent and duration of improvement. Since ptosis and ureteral kinking may be an important factor a ptosis belt with kidney pads was prescribed.

Case 7—R S, a married woman aged 48 was admitted to the Strong Memorial Hospital for the second time on April 10, 1939, complaining of severe headaches, blurring of vision, and substernal pains radiating into the left arm. On examination the blood pressure was found to be 240/148. The retinas showed edema of the disks, cotton wool exudates, and hemorrhages with narrow arteries and engorged veins. The heart was greatly enlarged. There was a gallop rhythm, a soft apical systolic murmur, and accentuated aortic second sound. There were no evidences of congestive failure. The kidneys were not palpable or tender. A urethral caruncle was seen at the meatus.

The urine showed moderate albuminuria, no sugar, acid reaction, and low specific gravity. The sediment showed 4 leukocytes per h p f in an uncentrifuged specimen, no r b c, and rare hyaline casts. Urine culture was sterile. The

phthalein test was 55 per cent in two hours, but only 15 per cent was excreted in the first half hour. The urea clearance test was 88 per cent, and the creatinine clearance 80 cc/min. The nonprotein nitrogen of the blood was 41 mg. The electrocardiogram showed abnormal ventricular complexes, and inversion of T waves in leads I and II. X-rays of the skull showed no abnormalities. A diagnosis of malignant hypertension was made.

The history recorded known elevations of blood pressure for twelve years, with anginal symptoms for six years. On previous admission in 1933 the blood pressure was found to be 140/90, though it had been observed by her family physician to have been much higher at times. The retinas on that admission showed very moderate hypertensive changes of the vessels, normal disks, no exudates or hemorrhages. The urine showed only a few leukocytes, 8-12 per h p f, with no albumin or sugar. Renal function was good then as now. There were no urinary symptoms except nocturia. The patient had never known of any renal disease and had had no toxic pregnancies.

A cystoscopy was performed by Dr W W Scott on April 19, 1939. He noted the urethral caruncle. The urethra was very tight. The bladder did not show much evidence of hypertrophy or trabeculation, but the pyelograms, shown in Fig 6, revealed evidence of dilatation of the pelves and blunting of the calyces of moderate degree, and in addition there was considerable ptosis and kinking of the ureters. The urethral stricture was well dilated. On the third day after this procedure the blood pressure had fallen to 180/130, as compared with 240/148 on admission. The patient felt better and was free from headaches and anginal symptoms. A belt was given for the renal ptosis, and she was discharged to her physician.

It is, of course, too soon to form judgment of the therapeutic value of the urethral dilatation and correction of ptosis. The report of this case is given as another example of the occurrence of urinary obstruction without symptoms and with good renal function in a patient who had presumably suffered from a so-called essential hypertension.

The last 3 cases indicate that one must revise the current conception of "essential" hypertension, which is that it is of nonrenal origin. Recently, attention has been drawn to narrowing of the renal arteries by atheroma as a cause of hypertension, resembling the experimental hy-

pertension of Goldblatt, by Williams and Harrison,⁶ Rosenberg, Keith, and Wagener,⁷ and Freeman and Hartley.⁸ The cases reported here point to urinary obstruction in the urethra or ureter, either by stricture or by kinking from ptosis. In Cases 5 and 6, both patients were known to have had previous urinary infection, but this was not active at the time of investigation. In these cases the hydronephrosis may have produced exaggerated effects, just as the hydronephrosis of pregnancy does. In Case 7 no other factor than urinary obstruction is known to exist, since there is no evidence of infection. One must consider the possibility that the kinking of the ureter in ptosis of the kidney may also affect the circulation through the renal artery.

Such cases as those recorded here show the importance of making a urologic study of cases of "essential hypertension," even though no evidence of urinary infection is present at the time. In the presence of mild obstructive lesions the urine may be quite normal and the function well maintained, though one may expect low specific gravity and possibly a lower-than-normal phthalein output in the first half hour, even though the total excretion is good.

In treatment of these conditions one must attempt to relieve strictures by dilatation, and to try to correct ptosis and kinking of the ureters. In cases of not too long-standing hypertension these measures offer hope of relief, provided arteriosclerosis is not too far advanced. While it is not likely that arteriosclerosis is the initial cause of the hypertension, one may strongly suspect that when long-standing hypertension produces arteriosclerosis, renal ischemia will become more marked, and its occurrence would probably aggravate the existing condition and establish a vicious circle. This offers a plausible hypothesis for the terminal malignancy of many long-standing and previously benign elevations of blood pressure.

In prophylaxis the indications are clear. All instances of infection of the urinary tract are to be regarded as po-

tentially serious, no matter how trivial they may seem at the time. Fortunately, the chemotherapy of these conditions has been vastly improved in recent years, particularly referring to the use of mandelic acid and sulfanilamide, and the appropriate control of urinary reaction. Some of the older agents are still deserving of occasional use such are hexamethylene amine, neutral acroflavine, and nearsphenamine. One learns that the strains of organisms in the urine differ among themselves in the way in which they respond to these agents, and several may have to be tried before the optimal one is found. In a given case different organisms may be found from time to time.

Apart from chemotherapy attention should be paid to focal infection, to diet, and to obstruction. Focal infections may be the portals of entry of the organisms which appear in the urine, and their eradication from tonsils, sinuses, teeth, and gallbladders should not be overlooked. Diet may have a great effect on urinary infection and calculus formation. Particularly important is its adequacy in vitamin A. It is well to see that the supply of this vitamin is adequate, and that the other essential factors are not lacking. All cases of urinary infection deserve urologic study.

Summary and Conclusions

1 Cases are described illustrative of the importance and seriousness, in view of the sequelae, of what may appear to be mild or trivial urinary infections. Cumulative insults over a period of years will frequently result in hypertension and ultimately in renal insufficiency.

2 The disastrous effects of pregnancy in such infections and their relation to the toxemias of pregnancy are strikingly illustrated in 1 case.

3 Hypertension may be the result of asymptomatic obstructive lesions of the urinary tract, even when the urine and renal function are normal. Cases are cited to show the importance of making pyelographic studies in patients with so-called "essential" hypertension.

4 Treatment of even the mildest forms of urinary infection demands the most careful general study of the patient. Chemotherapy may be immediately successful in clearing up infection, but this is not enough. Focal infection must be sought for and eradicated when found. Attention must be given to the diet, which must be adequate in vitamin content, particularly with reference to vitamin A, and adapted to maintain the appropriate reaction of the urine. These factors influence both the susceptibility to infection and to stone formation. Finally, obstructive lesions of the urinary tract must be discovered and corrected.

Discussion

Dr David M. Kydd, *Cooperstown, New York*—During the last several years there has been a renaissance of interest in hypertension and nephritis. Following the publication of the initial attempts at surgical intervention in the therapeutics of hypertension there has been a tremendous surge of investigative work. An evaluation of this mass of material leads to quite indefinite results because the attempt is being made to correct damage already done.

Dr McCann's contentions may easily be amplified. For example, Shaffer and Remsen report that of 20 cases of "chronic interstitial nephritis" only 5 had nephritis from some other cause than chronic pyelonephritis. Butler recently cited 2 cases of unilateral pyelonephritis with hypertension whose blood pressure became normal after nephrectomy. Peters states that at least 27 per cent of the toxemias of pregnancy that he has studied have some evidence of urinary infection. These examples from three different fields of medicine illustrate the importance of the subject.

The chronicity of pyelitis and pyelonephritis should be emphasized. These patients must be carefully observed for very long periods of time even after adequate chemotherapy. As Dr

McCann has pointed out, the cause of the infection must be found and corrected if feasible. No patient who has had a urinary infection should be discharged without definite evidence that the infection has permanently disappeared.

Pregnancy is to a certain extent a controllable factor. To allow a pregnancy to proceed in the face of a urinary infection or proceeding "toxemia" is to court disaster unless the situation receives extraordinarily careful and repeated evaluation, as evidence of irreparable damage may appear with explosive suddenness.

The fact that hypertension at its inception is remediable providing its cause can be eliminated should be emphasized. Further and repeated insults cause irreversible changes.

Hypertension and renal insufficiency are symptom complexes. Therefore, they probably have many causes. Nevertheless, the importance of the material presented by Dr McCann cannot be too strongly stated.

Dr Nathaniel Kutzman, *Buffalo, New York*—In view of the high incidence of hypertension and urinary tract infection in diabetes, we felt that a study of this group would be of value. Fifty female diabetics between the ages of 40 and 70, who were admitted to Dr Bowen's clinic and to the wards of the Buffalo General Hospital were investigated. They were taken consecutively. Most of them were ambulatory patients and had no urologic complaints. The results of this study are as follows:

Lower Urinary Tract

- I Cases studied—50
- II No urinary pathology—4 cases
- III Lower urinary tract involvement alone—14 cases
- IV Lower urinary tract involvement in all cases
 - A Chronic cystitis—32 cases
 - B Cystoceles—32 cases
 - C Stricture of urethra—18 cases

Cystoceles

- 1 Cystocele
Stricture of urethra 7 cases
Residual urine
- 2 Cystocele
Stricture of urethra 8 cases
No residual urine
- 3 Cystocele
No stricture 8 cases
Residual urine
- 4 Cystocele
No stricture 9 cases
No residual urine

Relationship to Hypertension

- I Lower urinary tract involvement alone
Normal blood pressure—5 cases
Hypertension—9 cases
- II Upper urinary tract involvement

- 1 No impairment of kidney function from either side was found in 32 cases
Normal blood pressure—14 cases
Hypertension—18 cases
- 2 (a) Leukocytes and bacteria from both kidneys with impairment of function (true bilateral pyelonephritis)—all 3 cases
Normal blood pressure—0 cases
Hypertension—3 cases
(b) No leukocytes, no bacteria, impaired function both sides (True medical nephritis)—2 cases
Normal blood pressure—0 cases
Hypertension—2 cases
- 3 Leukocytes, bacteria, impairment of function one kidney—11 cases
Normal blood pressure—3 cases
Hypertension—8 cases
- 4 Leukocytes, bacteria from both kidneys, normal function—4 cases
Normal blood pressure—1 case (few leukocytes with pure culture of anaerobic streptococci of both kidneys and bladder)
Hypertension—3 cases
- 5 Impairment of kidney function either unilateral or bilateral—17 cases
Normal blood pressure—4 cases
Hypertension—13 cases
Unable to obtain divided function—1 case
- 6 All cases but 2 who had impaired kidney function had either a hydronephrosis or leukocytes and bacteria coming from one or both kidneys
- 7 Three cases had unilateral hydronephrosis with normal function. Infecting organisms found were predominantly,
 - (1) Colon bacilli
 - (2) Enterococcus or Streptococcus faecalis
 - (3) Bacillus aerogenes
 - (4) Streptococcus hemolyticus

We find that there is evidence that infection and impairment of the urinary tract does occur quite frequently in the diabetic, perhaps to a greater degree than in a similar group of women who are not diabetic. We feel that many of these patients who have a lower urinary tract involvement alone, potentially have the makings of upper urinary tract disease, especially those having stricture of the urethra, cystitis, and residual urine. Back pressure with infection will undoubtedly involve the upper urinary tract. We have noted the high incidence of hypertension in bilateral infection of the kidneys with diminished function (true bilateral pyelonephritis). In unilateral infected kidneys with diminished function there is also a tendency toward hypertension (unilateral pyelonephritis). Infections and stasis play important roles in diminishing kidney function and hypertension.

THE PROGNOSIS OF NEPHRITIS AND NEPHROSIS IN CHILDHOOD

HERMAN SCHWARZ, M D , JEROME L KOHN, M D ,
and SAMUEL B WEINER, M D , New York City

(From the Pediatric Service of the Mount Sinai Hospital)

NEPHRITIS in childhood presents many interesting phases. There are many clinical, pathologic, and physiologic questions which must be solved. But paramount in importance to the active clinician and the patient is the question of the future course of the disease.

The prognosis in nephritis has interested us for many years. The recent advances in pathology, chemistry, and physiology have led to a better classification and broader understanding of nephritis. Our conception of the course of the disease has therefore improved. We have made a clinical study of all cases of nephritis and nephrosis admitted to the Pediatric Service of the Mount Sinai Hospital from 1911 to 1937. Twenty-five additional cases seen in the private practice of one of us are also included.

Material and Method

In 1925 a well-organized and independent follow-up clinic was established at the Mount Sinai Hospital. Since that time all patients with nephritis and nephrosis who were discharged from the hospital were referred to this clinic. Patients were seen at least twice a year, and more often when necessary. Delinquent patients were contacted and urged to come. If no response was obtained, they were visited by a social service worker. Prior to 1925 the Pediatric Service had its own follow-up clinic where these patients were seen at regular intervals.

In all, 394 patients with nephritis comprised the material of this study. We were able to follow 227 patients (57.6 per cent) after their discharge from the hospital. In a city as large as New York, this loss of material is to be ex-

pected since people change their residence very frequently.

Classification

It seems logical to us to divide these cases which we have followed into four clinical groups. Thus, of course, excludes (1) the acute infection of the kidney, secondary to bacteremia of various kinds, (2) the lesion of the kidney associated with the acute and chronic cases of pyelitis, (3) the kidney lesions secondary to developmental defects, to congenital deformity of the kidney, and to obstructive lesions in the urinary tract, (4) the occasional malignant hypertension nephritis in the young due to any of the above underlying conditions.

These above-mentioned clinical groups are made with the definite understanding that we are really unable to make pathologic diagnoses of kidney lesions at the bedside and that the diagnosis is actually a clinical one. They include (1) acute nephritis, (2) chronic nephritis of the nonprogressive type, (3) chronic nephritis of the clinical progressive type, (4) nephrosis.

These four major designations of Bright's disease in children are well understood and accepted by all pediatricians. The clinical and diagnostic criteria are quite uniform and are as follows.

Acute Nephritis—Usually follows or is concomitant with an infection. It is characterized by hematuria and albuminuria of short duration, usually not over six months, rarely a year or more. Edema of mild degree at the onset may or may not be present. Occasionally albuminuria and edema alone are present. Hypertension and convulsions are present in some cases at the onset of the disease.

McCann has pointed out, the cause of the infection must be found and corrected if feasible. No patient who has had a urinary infection should be discharged without definite evidence that the infection has permanently disappeared.

Pregnancy is to a certain extent a controllable factor. To allow a pregnancy to proceed in the face of a urinary infection or proceeding "toxemia" is to court disaster unless the situation receives extraordinarily careful and repeated evaluation, as evidence of irreparable damage may appear with explosive suddenness.

The fact that hypertension at its inception is remediable providing its cause can be eliminated should be emphasized. Further and repeated insults cause irreversible changes.

Hypertension and renal insufficiency are symptom complexes. Therefore, they probably have many causes. Nevertheless, the importance of the material presented by Dr McCann cannot be too strongly stated.

Dr Nathaniel Kutzman, *Buffalo, New York*—In view of the high incidence of hypertension and urinary tract infection in diabetes, we felt that a study of this group would be of value.  - (3) Bacillus aerogenes
 - (4) Streptococcus hemolyticus

We find that there is evidence that infection and impairment of the urinary tract does occur quite frequently in the diabetic, perhaps to a greater degree than in a similar group of women who are not diabetic. We feel that many of these patients who have a lower urinary tract involvement alone, potentially have the makings of upper urinary tract disease, especially those having stricture of the urethra, cystitis, and residual urine. Back pressure with infection will undoubtedly involve the upper urinary tract. We have noted the high incidence of hypertension in bilateral infection of the kidneys with diminished function (true bilateral pyelonephritis). In unilateral infected kidneys with diminished function there is also a tendency toward hypertension (unilateral pyelonephritis). Infections and stasis play important roles in diminishing kidney function and hypertension.

nephritis The sediment in 24 of these 25 cases was within the normal range The remaining case showed a pathologic sediment and on reinvestigation was shown to have a complicating hydro-nephrosis

Personally, we have taken a midway position There is no doubt that a certain number of acute nephritis cases recover completely and show no renal involvement even during subsequent severe infections However, we do see a certain number of patients who show albuminuria and casts during a subsequent infection In these patients we have wondered if the nephritis was again manifesting itself We have therefore added what we call the illness test which we believe is important clinically By the illness test we mean how well the kidney withstands infection after apparent recovery from acute nephritis

We also feel that clinically there are two distinct types of chronic nephritis One type is a nonprogressive disease which is not disabling The other type is progressive and often rapidly fatal Much longer periods of observation are necessary to establish the relationship of the nephritis of adult life to an attack in childhood It is notoriously difficult to obtain a history of acute nephritis in childhood from an adult 40 to 60 years old

The mortality in chronic progressive nephritis is very high and if these patients are followed for a long period of time an increasing number die within several years

The reports about nephrosis are difficult to classify because of the early confusion in terminology, and the error in diagnosing a case of chronic nephritis with edema as lipoid nephrosis Most studies in lipoid nephrosis show a 50 per cent mortality

Results

Acute Nephritis—In all 244 cases were seen Of these only 1 patient had two attacks which were separated by a period of two years The ratio of male to female was 2 to 1 Fifteen cases gave a

history of scarlet fever before the onset of the nephritis One case followed varicella, and 1 case followed an extensive burn In the remaining cases there was either a history of preceding respiratory infection or no history of any infection

Thirteen patients died (5.3 per cent) All of these children died soon after the onset of their nephritis It is interesting to note that 4 of the 13 fatal cases were one year old or under (Table 2) In 9 of the fatal cases there was some complicating factor, the nephritis alone not necessarily being the determining factor

We were able to follow 120 of the 230 living patients after their discharge from the hospital The period of follow-up varied from one to sixteen years with an average of about four to five years per patient (Table 3)

At their last examination 101 patients were completely recovered and showed no signs of any nephritic process as judged by general examination, urinalysis, and blood pressure The remaining 19 cases had to be divided into three groups In the first group of 7 cases definite chronic progressive nephritis was present within three years In the second group of 7 additional cases there was elevated blood pressure and some urinary abnormality These children show evidence of renal impairment but cannot as yet be classified as definite progressive chronic nephritis This second group has been observed from one to seven years and the children have remained in relatively good condition In the third group of 5 cases there

† Active cases of nephritis

‡ Tubular nephritis.

Chronic Nephritis of the Clinically Non-progressive Type—A patient was not considered cured of his acute nephritis when there was persistent albuminuria, hematuria, or casts for more than six months. Chronic clinically nonprogressive nephritis was diagnosed if the child remained in status quo with perhaps occasional albuminuria, at times increased blood pressure, or, in response to an infection, increased albuminuria. Perhaps nephropathia according to Aschoff would be the word applied to this condition. Just what the pathology of the kidney is, is not known, for the children do not die of this type of nephritis. Whether it makes for adult nephritis is also not known. Most frequently we believe that the nephritis is cured, but a long enough follow-up in cases of childhood nephritis has not been completed thus far.

Chronic Nephritis of the Clinically Progressive Type—Commonly called chronic progressive nephritis of childhood goes on rather rapidly to progressive anemia, azotemia, hypertension, and death. There may or may not be edema in these cases. Retention of nitrogen or other functional deficiencies may appear very soon. At least one year passes before we make up our minds whether or not to make this diagnosis definite. This is not the place to discuss why one case progresses and the other does not. Perhaps infectious foci have something to do with it. Perhaps the characteristics of the mesenchyme one is born with has something to do with it.

The criteria for the diagnosis of lipoid nephrosis have been described in two

previous communications by Schwarz and Kohn.

There were few cases that were difficult to classify after twelve months of observation. It was easy to say that the patient was suffering from chronic clinically progressive nephritis. However, it was often difficult to diagnose chronic clinically nonprogressive nephritis or the gradual recovery of the nephritis.

Literature

There are many reports of follow-up studies in nephritis varying from one- to ten-year periods. We have statistically summarized the most important contributions (Table 1).

There are two schools of thought relative to the ultimate outcome of acute nephritis. The first group believes that the disease is self-limited and distinct from chronic nephritis, rarely, if ever, passing into the latter. This school is headed by Aldrich and Lyttle. On the other hand, the second group, headed by Addis and Snoke, believe that a great many cases of acute nephritis become chronic. These latter workers consider acute glomerular nephritis as an initial or intermediate manifestation, and chronic nephritis as a terminal manifestation of the same disease. Addis and Snoke have pointed out the presence of pathologic urinary sediment findings by means of the Addis count in patients who are otherwise well following acute nephritis. Evidently there is disagreement on this point. Aldrich carefully did Addis counts on 25 patients representing a cross section of 250 recovered cases of acute

or nonprogressive at present. There is 1 additional case followed for three years, which has showed no evidence of nephritis for the past two years, as judged by general examination, urinalysis, and blood pressure. We might say this is the rare case which after a year of illness may recover entirely.

Obviously chronic nephritis is a grave illness. Over 50 per cent of the children afflicted with this disease die within one year of the onset of the illness. Very few (8 per cent) live more than five years. Extremely few show any evidence of arrest of the disease process. When recovery does take place it usually occurs in the first year of illness.

Lipoid Nephrosis—Since 1922 we have had 35 cases of lipoid nephrosis. A complete review of most of these cases has been presented by Schwarz and Kohn. To date 17 cases have ceased, 15 within one year of the onset of the disease. We had 5 postmortem examinations and these have confirmed our diagnosis.

Of the 18 living patients, 9 remained well from one to eleven years. There are 2 additional children who occasionally have some albuminuria and formed elements, but no edema. Three other children have gross albuminuria and periods of edema. One child followed for eleven years has been well and showed no abnormalities for years. At present she is approaching puberty and has some albuminuria and elevated blood pressure. It is difficult to decide whether or not this child is developing chronic nephritis.

We feel that lipoid nephrosis is a distinct disease. It has a mortality of about 50 per cent. A large number of the remaining 50 per cent recover from this disease within three to five years of its onset. Just what will happen to this group of presumably well children when they reach maturity, we cannot tell except by further observation.

Comment

We feel definitely that a great many cases of acute nephritis usually recover enough for perfect well-being and normal growth at development. With regard to

TABLE 5—TABLE SHOWING FOLLOW-UP STUDY OF 35 CASES OF LIPOID NEPHROSIS

complete cure of the kidney from a pathologic point of view, we hesitate to make a definite statement. Further follow-up and study of this group of patients into adult life are necessary to decide this important problem.

We also feel that there is a progressive type and nonprogressive type of chronic nephritis. The former is a rapidly fatal disease. The latter is compatible with general well-being for a long time.

Conclusions

1. A clinical study of 388 nephritis cases covering a twenty-five-year period is presented. Almost 60 per cent of these patients were followed after discharge from the hospital.

2. The cases fall into four clinical groups: (1) acute nephritis, (2) chronic nephritis—clinically nonprogressive type, (3) chronic nephritis—clinically progressive type, (4) lipoid nephrosis.

3. The immediate mortality in acute nephritis is 5 per cent. Eighty-five per cent seem to recover and remain free of nephritis as evidenced by general examination, urinalysis, and blood pressure, 10 per cent develop chronic nephritis, either progressive or nonprogressive clinically.

4. Patients admitted with a diagnosis of chronic nephritis have a mortality of over 50 per cent in the first year of illness. Only 8 per cent of our patients of this group have lived longer than five years. Only isolated cases show an arrest of the disease.

is occasional albuminuria only. We do not know if these children have non-progressive nephritis. They seem well, but we would prefer to observe them further and perhaps reinvestigate them before classifying them definitely.

We may therefore conclude that of this group of acute nephritis, 5 per cent died during the initial manifestation of their disease. Of those surviving, 84.1 per cent seemed to have recovered completely and showed no renal impairment after a fairly long follow-up. Another 42 per cent have still to be observed before being classified as recovered. The remaining 11.7 per cent showed definite renal impairment. Half may be definitely diagnosed as chronic progressive nephritis and the other half may also fall into this group.

What are some of the characteristics of those children who have developed chronic progressive nephritis? The urinary changes persist. Hypertension may or may not develop and occasional edema may be present. Nitrogen retention is not prominent. The child's appetite

and general condition is not satisfactory. There is loss of weight, edema develops, and the patient's turgor and color are poor. Usually progressive azotemia with or without hypertension ends the picture.

We cannot be certain that all the patients with acute nephritis did not have some previous kidney disease. It is possible, therefore, that these cases which develop into chronic nephritis were in reality an acute exacerbation of the latter disease when first seen. A definite opinion on this point is not possible. One must stress the point, however, that at the onset the cases that progress are indistinguishable from the ordinary run of acute nephritis.

Chronic Nephritis—Under acute nephritis we have discussed a group of patients who have developed chronic nephritis of a progressive or nonprogressive type. Another group of 115 patients on their first admission to the hospital were considered to have chronic nephritis. We were able to follow only 54 per cent of our cases after discharge.

Of the 62 patients followed, 37 have ceased (59.7 per cent). The duration of the disease in 30 of these children was less than one year (81 per cent). The remaining 25 children were still living from one to ten years after their initial attack (Table 4). Of the latter group only 5 children have lived longer than five years, and all have an active nephritic process. We have 3 recent cases which have improved after one year, so that we have to classify them as inactive.

FRIEDREICH'S ATAXIA ASSOCIATED WITH DIABETES MELLITIS

N S SCHLEZINGER, M D , Philadelphia, and KURT GOLDSTEIN, M D ,
New York City

(From the Neurophysiological Laboratory, Montefiore Hospital, New York City)

THE neurologic disorder known as Friedreich's ataxia is generally considered to be a heredodegenerative disease of the central nervous system. Although it is doubtful whether a definite and rigid distinction between the spinal (Friedreich)¹ and the cerebellar (Marie)² forms of hereditary ataxia is justifiable, the cases that we are about to describe would, in such a classification, be grouped as instances of Friedreich's disease. The consensus favors the origin of this neurologic disorder, wholly or chiefly, on the basis of an anomaly or predisposition of the central nervous system, but the exact manner whereby it has been propagated has not as yet been clearly determined. The course of the disease is progressive and no effective therapy is available.

Although the introduction of insulin as a specific and effective mode of therapy in diabetes has resulted in a radically altered prognosis, the etiology and pathology of this endocrine disorder, in many respects, have remained enigmatic. Therefore, when one finds linked together two conditions such as Friedreich's ataxia and diabetes mellitus, a careful study of the individual cases is indicated with the hope of possibly discovering some unknown factors which may lead to a better understanding of either one or both of these conditions.

The subject of "neural and extra-neural anomalies" occurring in Friedreich's ataxia has been reviewed in detail by Alpers and Waggoner.³ However, they made no mention of the rare occurrence of diabetes mellitus as an associated disorder. A survey of the literature reveals that there have been 18 cases described in which such an association has been observed. We are able to

add 2 cases to this series making a total of 20 cases (Table 1).

Case Reports

Case 1—M D, female, aged 13, born in U S A., was first admitted to Montefiore Hospital on August 28, 1930, with history of unsteadiness in walking since 6 years of age, neurologic picture characteristic of Friedreich's ataxia and associated with evidence of status dysraphicus and polyglandular endocrine dysfunction, gradual progression of neurologic symptoms with development of diabetes mellitus at 15 years of age.

Chief complaint was the inability to walk straight. Family history revealed that her parents were second cousins and that in Russia there existed a family group resulting from a marriage between the father's brother and mother's sister. (Efforts to communicate with this collateral branch of the family have been unsuccessful.) Patient was the youngest of 5 siblings. One brother had infantile paralysis in childhood. One sister (Case 2) had an illness similar to that of the patient.

Birth and early development of patient seem to have been essentially normal. Illnesses during infancy consisted of measles at 4 years and diphtheria at 5 years. A tonsillectomy was performed at 6 years of age. School attendance started at 5½ years of age and excellent progress was made by the patient. Onset of the present illness occurred between 5 and 6 years of age during convalescence from diphtheria, when it was noticed by other people that the patient was unsteady in walking and had slight difficulty in using her hands. These symptoms gradually became more marked and at 8 years of age various hospital clinics were visited. Diagnosis at that time was "St. Vitus' Dance" but treatment was ineffective. At 10 years of age patient was admitted to the Neurological Institute where a diagnosis Friedreich's ataxia was made. Psychometric examinations revealed an I Q of 114. Laboratory studies were negative. Subsequently, treatment consisted largely of physiotherapy but symptoms progressed es-

5 In our series of lipoid nephrosis the mortality was 50 per cent in the first year. Nine of the remaining patients recovered after several years of illness. The disease is distinct from chronic nephritis.

THE UNITED STATES PHARMACOPŒIAL CONVENTION

This is the second call for the Decennial Meeting of the Convention for the Revision of the *Pharmacopœia of the United States of America*, to be held at Washington, D. C., beginning May 14, 1940.

In compliance with the provisions of the Constitution and Bylaws of the United States Pharmacopœial Convention, I hereby issue this second call to the several bodies entitled under the Constitution to representation therein to appoint three delegates and three alternates to the Decennial Meeting of the Convention for the Revision of the *Pharmacopœia of the United*

States of America, which is to meet in Washington, D. C., on May 14, 1940.

WALTER A. BASTEDO, M.D., *President, United States Pharmacopœial Convention*

NOTICE—In order that the records may be brought up-to-date and checked, that card files may be prepared, and that the other functions of the Committee on Credentials may be performed, it is desirable that the credentials of all delegates appointed to attend this decennial meeting shall be in the hands of the Secretary, Mr. L. E. Warren, 2 Raymond St., Chevy Chase, Maryland, not later than March 15, 1940.

AMERICAN BOARD OF INTERNAL MEDICINE, INC.

The American Board of Internal Medicine will conduct oral examinations just previous to the meeting of the American College of Physicians in Cleveland and just in advance of the meeting of the American Medical Association in New York City.

Applicants who have successfully passed the written examination and plan to take the oral examination in 1940, should advise the office of

the Secretary at least six weeks in advance of the date of the examination they desire to take.

The next written examination for 1940 will be given on October 21. Applications for this examination must be filed in the Secretary's office by September 1.

Application forms may be obtained from Dr. William S. Middleton, Secretary-Treasurer, 1301 University Avenue, Madison, Wisconsin.

WHERE WE ARE HEADED FOR

One out of every 22 children born today will become a patient in a mental hospital, according to present authoritative data. According to the same data, 1,000,000 children now in public schools will suffer a mental breakdown some time in their lives, unless something is done about it. This was stated in a recent lecture by Dr. Walter L. Treadway, chief medical officer of the U. S. Public Health Service and lecturer in psychiatry in the University of California Medical School, as reported in *California and Western Medicine*.

The number of mental cases per one hundred thousand population is now more than four times what it was eighty years ago. It is now necessary to spend more than \$200,000,000 annually for mental patients who require segregation.

Regarding the treatment of mental ailments

Doctor Treadway said, "If physicians of today and tomorrow are to fulfill their responsibility, then it is necessary that they take cognizance of the forces at work in their community as they affect their patients. Mass study of such forces, however, is a function peculiar to the discipline of epidemiology and sociology.

"The recognition, care, and treatment of mental illness implies a knowledge of these conditions. While it is true that no state legislature has kept pace with the needs of the mentally ill, nevertheless in those states where mental health administration is directed by medically trained persons, the facilities and public policies affecting the mentally ill are far ahead of those jurisdictions where hospital facilities alone represent the assumed total of a community's obligation and responsibility toward mental disease and disorder."

TABLE 1—SERIES OF CASES HAVING FRIEDREICH'S ATAXIA ASSOCIATED WITH DIABETES MELLITUS—20 CASES

	Author	Sex	Age at Ataxia	Onset of Diabetes	Result	Neuropathology	Remarks
1	Rossi ²⁰ (1893)	F		18?	Death	Typical myelopathy circumscribed sclerosis in medulla scattered areas of degeneration subcortically including basal ganglia	Friedreich's ataxia in both cases existed long before onset of diabetes
2				16?			
3	Burr ²¹ (1894)	F	10	25?	Death	Typical myelopathy brain pathology not given	A brother also had Friedreich's ataxia
4	Best ²² (1899)	F	7	14	Death in coma		Acute onset of diabetes two weeks before death therapy ineffective
5	Mingazzini and Peruzzi ²³ (1904)	M	10	17	Death in coma	Typical myelopathy, slight rarefaction of periventricular fibrous network in medulla in mesencephalon found nothing noteworthy	A sister also had Friedreich's ataxia was physically underdeveloped and showed menstrual irregularities
6	Meltzer ²⁴ (1908)	M	26	27	Death	Typical myelopathy brain pathology not given (Schloss ¹¹)	Diabetes temporarily controlled by an almost complete carbohydrate free diet pancreas showed almost complete absence of islet tissue
7	Frey ²⁵ (1912)	F	7	22	Death		Terminal inanition with tachycardia and arrhythmia
8		F	5	34	Death in coma	Typical myelopathy brain pathology not given	Had irregular menses and an infantile uterus Two brothers and one sister also had Friedreich's ataxia
9	Kalinsky ²⁶ (1929)	M	14	31	Death at 31 years of age	Typical myelopathy brain pathology not given	Two brothers and one sister also had Friedreich's ataxia
10	Mollaret ¹⁹ (1929)	F		31	Living at 33 years of age		Single episode of severe diabetes with coma and followed by subsidence ultimately requiring no specific therapy
11	Schloss ¹¹ (1932)	F*	21	26	Living at 27 years of age		Had diet plus insulin therapy but diabetes difficult to control at times
12		M*	15		Living at 24 years of age		Showed slight glycosuria after test with high carbohydrate diet no progression of diabetic symptoms
13	Wichtl ¹⁵ (1933) (also Basch ¹⁰)	M	5	8	Death in coma at 12 years of age	Typical myelopathy marked degenerative change in dorsal vagus nucleus and in dentate nuclei basal ganglia and tuber cinereum negative	Diabetes required progressively increasing insulin dosage epileptic seizures noted at 9 years of age
14	Curtius Schoenberg and Stoerring ¹² (1935)	F*	7	12	Living at 20 years of age		Had irregular menses diabetes controlled by diet and progressively increasing insulin dosage
15		F*	16	22	Living		Diabetes controlled by diet plus insulin had epileptic seizures
16	Lunedei and Liesch ¹⁶ (1935)	F*	14	14	Death at 17 years of age	Typical myelopathy	Had Simmonds disease and cardiorespiratory syndrome
17		F*	15	35	Death at 36 years of age		Diabetes treated by diet had amenorrhea and cardiorespiratory syndrome
18		M*	17	38	Living at 41 years of age		Diabetes controlled by diet plus insulin therapy early in course of illness showed positive blood Wassermann and reaction which became negative after specific arsenic therapy had cardiorespiratory syndrome
19	Schleizinger and Goldstein	F*	6	15	Living at 21 years of age		Diet plus insulin therapy but diabetes difficult to control at times has evidence of multiple endocrine hypofunction
20		F*	15	21	Living at 28 years of age		Diet plus insulin therapy but diabetes difficult to control at times has physical underdevelopment, infantile uterus and irregular menses

* Siblings.

pecially the unsteadiness in walking, so that patient often tripped while walking. There was history of occasional urinary incontinence when laughing. Menstruation started at 11½ years of age and was regular in all respects.

Physical Examination—Patient appeared to be a well-nourished, well-developed, cheerful, intelligent girl who was ambulatory and co-operated well during examination. There was a slight kyphoscoliosis of the thoracic spine. Feet showed pes cavus with talpes equinovarus bilaterally and spontaneous extension of the great toes. The metacarpophalangeal joint of the left fourth digit was markedly depressed. Heart, lungs, and abdomen were grossly normal. Blood pressure was 80/55.

Neurologic Examination—Gait broad based and ataxic. Slight incoordination in finger to nose test, marked incoordination in heel to knee test noted bilaterally but more so on the left.

Rebound phenomenon present in all extremities. There was definite paresis of lower extremities. Pseudoathetotic movements of fingers and an intention tremor of hands and head were elicited. There was tendon areflexia in all extremities. Abdominal reflexes were present and active. Babinski and Chaddock signs noted bilaterally. Disturbances in sensation consisted of loss of position sense in the toes, pallesthesia in the lower extremities, and an irregular distribution of hypesthesia for superficial modalities. Cranial nerve functions were normal with no evidence of dysarthria or nystagmus.

Laboratory Data—Urinalysis and blood count normal. Spinal fluid clear and colorless with negative Pandy and a total protein of 40.2 mg. Blood and spinal fluid serology was negative for evidence of syphilis. Roentgenography of hands showed the left fourth metacarpal to be about half the length of that on the right and a similar but less marked shortening of the left third metacarpal bone was noted.

Course—During initial period of hospitalization there was no noticeable change in patient's condition. She was discharged on January 13, 1931, as unimproved. During the interval at home there was a gradual progression of neurologic signs accompanied by occasional sudden exacerbations lasting one or two days when the patient would feel much weaker and be unable to walk. After April, 1932, it was noted that patient was unable to walk without support because of the marked ataxia and weakness of the legs.

In August, 1932, there appeared polydipsia, polyphagia, and polyuria. These symptoms rapidly increased in intensity and were accompanied by a gradual loss of weight. A diagnosis

of diabetes mellitus was made shortly before re-admission on November 5, 1932. Examination showed some fullness of neck suggestive of an enlarged thyroid gland, a seborrheic dermatitis, and an increased intensity of ataxia. Other signs were same as noted previously. Laboratory studies revealed glycosuria of 1 to 3 per cent, fasting blood sugar of 182 and blood urea nitrogen of 13.7 mg., B.M.R. of -31 per cent, normal gastric analysis. During second period of hospitalization constipation was a constant feature and was associated with occasional acute episodes of abdominal pain and vomiting suggestive of appendicitis. There was considerable fluctuation in the degree of hyperglycemia but at time of discharge on July 1, 1933, stabilization was accomplished on the basis of a diabetic diet (C 125, P 75, F 125) plus insulin (UX and UV). Amenorrhea for a period of three months occurred during her stay in the hospital and recurred immediately after discharge, persisting for three years until July, 1936. During interval preceding her third admission increased general weakness and ataxia were noted. In addition there appeared to be a gradual diminution in the size of the muscles of the arm and the inner portion of both thighs. Blurring of vision was noted at times.

Patient was re-admitted to the Montefiore Hospital on December 26, 1934, and hospitalization has been continuous ever since. Physical examinations during this time have shown, besides signs previously observed, an asymmetry in the size of the breasts and an infantile uterus. Neurologic examinations have shown increasing ataxia, weakness, and dorsal column sensory disturbances in the legs. The appearance of the fundi has been considered suggestive of temporal pallor. Laboratory studies have revealed sugar tolerance 186 (fasting), 302 (one-half hr.), 352 (one hr.), 348 (two hr.), 270 (three hr.), 238 (four hr.), blood cholesterol 200 mg and cholesterol esters 168 mg., B.M.R. -27 per cent. X-ray of skull showed sella turcica to be normal in size with no other pathologic changes observable. X-ray of the gastrointestinal tract showed delayed gastric emptying. During her present period of hospitalization patient has had recurrent episodes characterized by colicky abdominal pain, abdominal distention, nausea, and marked constipation. Patient has also occasionally complained of headache with transient blurring of vision. In November, 1935, she complained of a dull pain over the distribution of the lower two branches of the left trigeminal nerve which subsided after several days and was not accompanied by objective sensory disturbances on the face. Reappearance

pairment of position sense were noted in the distal portions of both lower extremities, more so on the left. Speech of patient was nasal in character and suggestively scanning. A ticlike retraction of the left angle of the mouth was present intermittently. Cranial nerve functions otherwise were normal.

Laboratory Data—Urinalysis showed a variable degree of glycosuria. Blood count was normal. Fasting blood sugar was 181 mg and urea nitrogen 10.5 mg. Spinal fluid was clear and colorless with normal manometric curve, negative Pandy, and total protein of 20.1 mg. Blood and spinal fluid serology was negative for evidence of syphilis. B. M. R. was +3. Psychometric examination revealed I. Q. of 93.

Course—During initial period of hospitalization considerable difficulty was encountered in controlling patient's hyperglycemia. Diet and insulin were varied but stabilization could only be temporarily achieved. Frequently fractional urine specimens would show glycosuria which would persist in spite of increased dosage of insulin and would be associated with attacks of hypoglycemia. Rapid fluctuations in the blood sugar level occurred at times. Neurologic examination in June, 1933, showed exaggeration of signs previously noted. Patient also experienced paresthesia in left arm at irregular intervals. On several occasions she complained of blurred vision which was transient in character. Period of amenorrhea present before admission was terminated by onset of menstruation a few days after admission. In September, 1934, an acute illness developed in the form of right pleurisy with effusion. This illness was afebrile and at the end of a month effusion had disappeared. Sputum examination and guinea pig inoculation of pleural fluid were negative for evidence of tuberculosis as was also x-ray of lungs. On November 10, 1934, patient was discharged, condition unimproved.

During the interval of a year at home patient became progressively weaker and ultimately was unable to walk without support. When attempting to walk she often fell and suffered many bruises. Paresthesia in the form of tingling sensations in the left hand radiating up to the elbow recurred intermittently, was usually noted at night, and seemed to subside after increases in dosage of insulin. When re-admitted on November 10, 1935, physical examination revealed same features noted on previous admission. Significant neurologic findings were inability to walk without support, marked ataxia in all extremities, dysidiadochinesis and rebound phenomenon, nasal, slightly dyssynergic speech, ataxic, intention tremors of head,

tongue, and face, abdominal reflexes normally active, deep areflexia except for diminished jaw jerk, bilateral Babinski and Chaddock signs, generalized hypotonicity and motor weakness, more so in lower extremities, pallanesthesia in both legs and loss of position sense in the feet, slight uniform pallor of optic disks with slight uniform constriction of peripheral visual fields but with normal visual acuity. There was no gross evidence of intellectual impairment but pathologic sensitivity was noted. There was a history of occasional difficulty in starting act of urination and a history of chronic constipation. Noteworthy laboratory findings during second period of hospitalization were fasting blood sugar of 170 mg., cholesterol 248 mg. and cholesterol esters 126 mg., negative x-rays of skull and chest. While hospitalized, amenorrhea recurred at irregular intervals and persisted for periods as long as six months. On one occasion patient suddenly developed nausea, right-sided abdominal pain and leukocytosis which subsided after a few days. Despite fluctuations in level of hyperglycemia and occasional hypoglycemic reactions a fairly satisfactory stabilization was achieved by means of diet (C 130, P 80, F 100) plus insulin (UXV and UX). She was discharged on August 28, 1937, condition unimproved. Since then examination at regular intervals in O. P. D. has shown no significant change in her condition.

Comment

The anamnestic data in these cases reveals that the onset of the neurologic disorder occurred following diphtheria in Case 1 and at the time of puberty in Case 2. There have been described in Friedreich's ataxia what appear to be precipitating etiologic factors such as acute infections,⁴ trauma,⁵ puberty,⁶ etc. These factors may account for the fact that cases such as ours do not conform with the observation of "homochronicity" emphasized by Hanhart.⁷ The genetic data in these cases show the existence of parental consanguinity and this may be regarded as favoring the development of heredodegenerative disease. It is unfortunate that a duplicate collateral branch of this family is inaccessible for investigation.

The characteristic semiology of Friedreich's ataxia is well demonstrated in both cases and needs no emphasis. However, the existence of certain unusual

of menstruation in July, 1936, was marked by a shortening of interval to three weeks, by menorrhagia, and by dysmenorrhea in the form of sharp, stabbing pelvic pains for one week preceding menstrual periods. Fluctuations in the degree of hyperglycemia have occurred suddenly and resultant difficulty in controlling diabetes has been experienced. Recently it has been possible to stabilize patient on basis of diet (C 130, P 80, F 100) plus insulin (UXX and UXV). At present neurologic picture is essentially that of a far advanced case of Friedreich's ataxia with exaggeration of neurologic signs already noted.

Case 2—R D, female, aged 22, born in England, first admitted to the Montefiore Hospital on June 18, 1932, with history of difficulty in walking which appeared with menarche at 15 years of age, developed diabetes mellitus at 21 years of age, neurologic picture characteristic of Friedreich's ataxia and associated with evidence of polyglandular endocrine dysfunction, gradual progression of neurologic symptoms.

Complaints were difficulty in walking for six years and diabetes for nine months. Family history is same as that described for her sister (Case 1). Birth and early development were apparently uneventful. Illnesses during infancy and childhood consisted of incision of an infected birthmark in left axilla at 3 months, measles at 6 years, pertussis at 10 years. A tonsillectomy was performed at 10 years of age. School attendance started at 6 years of age and normal progress was made ending with graduation from high school at 18 years of age. Except for occasional cramplike pains in the muscles of her legs patient was in good physical health previous to the onset of her present illness. She is said to have always been "nervous" and emotionally unstable with irritability and violent temper as especially prominent features of her personality.

Onset of the present illness occurred at 15 years of age and was temporarily associated with the onset of menstruation. Difficulty in walking downstairs was first noted and was ascribed to stiffness of the knees and inaccurate measuring of steps. At 17 years of age difficulty in running was noted and was due to stiffness of legs together with a tendency to stumble. At 18 years of age, while employed as a stenographer, patient began to experience difficulty in walking due to poor balance and lack of proper muscle control. She was able to continue her routine activities until October, 1929, when she was accidentally struck by an automobile. Although unconscious for one hour, examination

showed no fractures and except for "mental shock" no untoward reaction was noted. Difficulty in walking gradually became more marked. There also appeared to be some unsteadiness in holding objects in hands. In September, 1930, when she was 20 years of age, patient was examined in this hospital and significant findings at that time were general physical underdevelopment, ataxic gait, Friedreich's feet, impaired position sense in feet, Babinski sign bilaterally. A diagnosis of Friedreich's ataxia was made. During the year previous to admission a change in patient's personality was noted in the form of exaggerated shyness and reserve, self-consciousness and fear of being observed. She restricted her activities because of a fear of falling and when walking outside the home had to be assisted. Paresthesia in the left forearm described as "pins and needles" occurred intermittently.

In September, 1931, shortly before developing a hordeolum, patient noticed increased thirst and polyuria. Urinalysis revealed glycosuria and a diagnosis of diabetes mellitus was made. Therapy at first consisted of diet plus insulin but latter was stopped in March, 1932. Polyuria soon recurred and symptoms of marked acidosis rapidly appeared. At this time patient was admitted to another hospital, remained there for two weeks, was discharged with diabetes controlled by means of diet plus 20 units insulin daily. Menses of patient were always regular until acidosis occurred but then amenorrhea appeared.

Physical Examination—Patient was a well-nourished but underdeveloped female of uniformly small stature who appeared to be several years less than her chronologic age. There seemed to be a slight fullness of the neck but the thyroid was not palpably enlarged. Skeletal changes consisted of a slight lumbar scoliosis and a pes cavus with talipes equinovarus bilaterally. There was cutis marmoratus of both lower extremities and coolness of feet. Heart, lungs, and abdomen showed no gross abnormalities. Gynecologic study revealed an infantile uterus and a nonspecific vaginitis. Blood pressure was 120/80.

Neurologic Examination—Gait was markedly ataxic and patient had great difficulty in walking without support. There was marked incoordination in movements of all extremities. Rebound phenomenon and dysidiadochokinesia were present. Pseudoathetosis of fingers was noted. Tendon areflexia was noted in all extremities. Abdominal reflexes were present but diminished. Babinski and Chaddock signs were elicited bilaterally. Pallesthesia and im-

"Friedreich's ataxia and status dysraphicus"

The concept of diabetogenic myelopathy is entertained on the basis of a comparison with dorsolateral sclerosis of the spinal cord which occurs in association with pernicious anemia. However, this hypothesis is a very unlikely one. It is opposed by the fact that the association of Friedreich's ataxia with diabetes mellitus is rare and by the fact that in all cases where this association has occurred the onset of the former disease has antedated the latter, usually by a period of years.

Neurogenic diabetes has been an established fact since the celebrated experimental observation of Claude Bernard. Until recently, however, there has been little progress made toward a better understanding of the mechanism involved. There has been a gradually increasing recognition that the hypothalamus is the site of important supra-segmental centers of the vegetative nervous system.¹³ Certain experimental observations^{14,15} have revealed the existence of a neural center in the hypothalamus which influences carbohydrate metabolism. Vonderahe,¹⁶ on the basis of a pathologic study of clinical cases with diabetes mellitus, has constructed diagrammatically a neural reflex pattern which he believes may be utilized as an anatomic basis for the hypothesis of neurogenic diabetes.

Examination of the case reports in this series from the standpoint of data relevant to the concept of neurogenic diabetes discloses a relative dearth of significant material. In many of the cases the existence of diabetes was barely mentioned and received little attention clinically or pathologically. It is particularly unfortunate that in those cases where autopsies were performed neuropathologic examination was largely limited to the spinal cord. In only 2 cases^{17,18} was there specific mention of a microscopic study of the hypothalamus and in both the findings were interpreted as being normal. Clinically there were a number of instances in which circulatory and

respiratory disturbances occurred.¹¹ These changes usually have been ascribed to involvement of vegetative centers in the medulla.¹⁹ In 3 cases^{17,18,20} there were noted degenerative changes in the medulla which affected the vagal nuclei and adjacent neural tracts. It is not possible on the basis of these observations to either prove or disprove the hypothesis of neurogenic diabetes. One should be especially guarded in any attempt to exclude the hypothalamus from further consideration since it appears that the paraventricular and other hypothalamic nuclei have not been subjected as yet to the detailed histopathologic study which should be considered mandatory in all such cases.

The not infrequent occurrence of hyperglycemia in cases of acromegaly²¹ and of Cushing's syndrome²² would appear to be clinical examples of diabetes mellitus associated with hyperpituitarism and therefore in accordance with the experimental observations of Houssay and Biasotti.²³ On the other hand, it must be realized that there have been reports of clinical cases in which diabetes mellitus has been found to be associated with hypopituitarism.^{24,25} Gibson and Fowler²⁶ state that their clinical findings do not agree with the experimental findings. Evidence of endocrine dysfunction not uncommonly has been recorded as occurring in association with Friedreich's ataxia and has manifested itself in such forms as infantilism,²⁷ myxedema,²⁸ genital hypoplasia,²⁹ etc.³⁰ Data of this character seems to show that endocrine disorders occurring in patients with Friedreich's ataxia are almost always due to hypofunction of one or more of the glands of internal secretion and this is well demonstrated in our cases (vide supra). In view of such observations, it would appear that the diabetes occurring in cases of Friedreich's ataxia is best explained on the basis of hypofunction of the islets of Langerhans either primarily or secondarily produced. It is interesting to note that in only 1 case³¹ in this series was the pancreas found to show histopathologic evidence of disease.

neurologic phenomena may be pointed out. Optic atrophy is present in both cases and has been recorded by other authors.⁸ The episodic occurrence of facial paresthesia in Case 1 may be due to a lesion affecting the nucleus of the trigeminal nerve such as has been observed by Spiller.⁹

Extraneural anomalies are more common than generally considered and are deserving of the attention that has been given to them.³ Multiple malformations are seen in our Case 1 in the form of breast asymmetry, muscle atrophy, and metacarpal abbreviation. Described as anomalies in cases of Friedreich's ataxia have been a variety of manifestations of endocrine imbalance. In our cases there is evidence of endocrine dysfunction in the form of immature body development in Case 2, markedly lowered basal metabolic rate in Case 1, infantile uterus and periods of amenorrhea in both cases. In addition, a striking feature in both cases is the apparently specific limited concurrence of diabetes mellitus with Friedreich's ataxia, and this constitutes the problem toward which most of our attention will be directed.

Discussion

A review of all the cases in which Friedreich's ataxia has been associated with diabetes mellitus reveals certain noteworthy features (Table 1). Familial incidence is shown strikingly in the cases reported by Lunedei and Liesch¹⁰ and exists in our cases. It is important to note that in some families more than one member has been affected by Friedreich's ataxia without necessarily having had diabetes but that the latter, when present, has always been associated with the former. There are 13 females and 6 males in this series with the sex undetermined in 1 case. The number of cases is too small for this differential sex incidence to be considered of definite significance but it may be contrasted with the supposedly higher incidence of Friedreich's ataxia in males. In all but 2 cases the onset of the neurologic disorder occurred during the first two dec-

ades of life. The onset of diabetes varied between 8 and 38 years of age and was antedated in all cases by the onset of Friedreich's ataxia, usually by an interval of many years. The onset of diabetes was relatively acute in most cases and the condition was usually too severe to be controlled by diet therapy alone. Until the introduction of insulin therapy death in most instances was due to diabetic coma. By means of diet plus insulin therapy it has been possible to control the diabetes and thus prolong life in these cases. Lability of the glycemie level and sudden alterations in insulin sensitivity were noticeable in our cases and caused difficulty in the maintenance of adequate therapy. Similar difficulty was noted by Schloss¹¹ in one of his cases.

As shown by our survey of the literature, the unusual combination of Friedreich's ataxia and diabetes mellitus seems to have occurred more frequently than at first suspected. Various explanations that might be offered for the concurrence of these two diseases are coincidence, hereditary predisposition, chromosome linkage, diabetogenic myelopathy, neurogenic diabetes. The incidence, as has been pointed out by Schloss¹¹ and by Curtius, Stoerring, and Schoenberg,¹² is greater than can be explained on the basis of coincidence. Besides, the familial occurrence of this specific combination is such as to preclude any possibility of coincidence.

Hereditary predisposition and chromosome linkage may be considered together as hypotheses which, although differing in point of emphasis, can be used to explain the familial incidence of this combination without the necessity of directly linking the two conditions to each other in a pathogenic manner. Such a point of view is supported by the occurrence of many extraneural anomalies in cases of Friedreich's ataxia which can only be explained on the basis of defects in various body systems other than the central nervous system. The idea of genetically correlated defects has been emphasized by Curtius, Stoerring, and Schoenberg¹² who refer to their cases as

"Friedreich's ataxia and status dysraphicus"

The concept of diabetogenic myelopathy is entertained on the basis of a comparison with dorsolateral sclerosis of the spinal cord which occurs in association with pernicious anemia. However, this hypothesis is a very unlikely one. It is opposed by the fact that the association of Friedreich's ataxia with diabetes mellitus is rare and by the fact that in all cases where this association has occurred the onset of the former disease has antedated the latter, usually by a period of years.

Neurogenic diabetes has been an established fact since the celebrated experimental observation of Claude Bernard. Until recently, however, there has been little progress made toward a better understanding of the mechanism involved. There has been a gradually increasing recognition that the hypothalamus is the site of important supra-segmental centers of the vegetative nervous system.¹³ Certain experimental observations^{14, 15} have revealed the existence of a neural center in the hypothalamus which influences carbohydrate metabolism. Vonderahe,¹⁶ on the basis of a pathologic study of clinical cases with diabetes mellitus, has constructed diagrammatically a neural reflex pattern which he believes may be utilized as an anatomic basis for the hypothesis of neurogenic diabetes.

Examination of the case reports in this series from the standpoint of data relevant to the concept of neurogenic diabetes discloses a relative dearth of significant material. In many of the cases the existence of diabetes was barely mentioned and received little attention clinically or pathologically. It is particularly unfortunate that in those cases where autopsies were performed neuropathologic examination was largely limited to the spinal cord. In only 2 cases^{17, 18} was there specific mention of a microscopic study of the hypothalamus and in both the findings were interpreted as being normal. Clinically there were a number of instances in which circulatory and

respiratory disturbances occurred.¹¹ These changes usually have been ascribed to involvement of vegetative centers in the medulla.¹⁹ In 3 cases^{17, 18, 20} there were noted degenerative changes in the medulla which affected the vagal nuclei and adjacent neural tracts. It is not possible on the basis of these observations to either prove or disprove the hypothesis of neurogenic diabetes. One should be especially guarded in any attempt to exclude the hypothalamus from further consideration since it appears that the paraventricular and other hypothalamic nuclei have not been subjected as yet to the detailed histopathologic study which should be considered mandatory in all such cases.

The not infrequent occurrence of hyperglycemia in cases of acromegaly²¹ and of Cushing's syndrome²² would appear to be clinical examples of diabetes mellitus associated with hyperpituitarism and therefore in accordance with the experimental observations of Houssay and Biasotti.²³ On the other hand, it must be realized that there have been reports of clinical cases in which diabetes mellitus has been found to be associated with hypopituitarism.^{24, 25} Gibson and Fowler²⁶ state that their clinical findings do not agree with the experimental findings. Evidence of endocrine dysfunction not uncommonly has been recorded as occurring in association with Friedreich's ataxia and has manifested itself in such forms as infantilism,²⁷ myxedema,²⁸ genital hypoplasia,²⁹ etc.³⁰ Data of this character seems to show that endocrine disorders occurring in patients with Friedreich's ataxia are almost always due to hypofunction of one or more of the glands of internal secretion and this is well demonstrated in our cases (vide supra). In view of such observations, it would appear that the diabetes occurring in cases of Friedreich's ataxia is best explained on the basis of hypofunction of the islets of Langerhans either primarily or secondarily produced. It is interesting to note that in only 1 case³¹ in this series was the pancreas found to show histopathologic evidence of disease.

A similar scarcity of pathologic evidence of pancreatic disease in cases of acromegaly and pituitary basophilism with diabetes has been pointed out by Cushing³²

The hypophysis has been shown to have an important influence on many endocrine glands through the action of its tropic hormones. Therefore, the polyglandular hypofunction noted in cases of Friedreich's ataxia may be a result of a primary hypofunction of the hypophysis. Favoring the inclusion of diabetes mellitus in such a general hypothesis would be the evidence presented by Anselmino, Herold, and Hoffmann³³ for the existence of a pancreatropic hormone. In this connection it may be well to point out that Houssay³⁴ has emphasized the extrapancreatic nature of the "diabetogenic" action of the hypophysis. The close relationship that exists between the hypophysis and the hypothalamus has been recognized for many years and has been the subject of considerable speculation by endocrinologists and neurologists. The presence of intimate anatomic-physiologic connections between these two structures has been well established. The hypophyseoportal vascular system was described by Popa and Fielding³⁵ and the neural connections via the infundibular stalk have been re-emphasized by Pines.³⁶ Increasingly significant roles have come to be ascribed to both the hypophysis and the hypothalamus as the respectively dominant endocrine and neural structures which are concerned in controlling the visceral functions of the body. It is not surprising that the conception of a neuroendocrine system has been evolved in which the hypophysis-hypothalamic region is assigned the dominant role.

Our personal observations as well as a review of those in the literature do not permit us to arrive at any definite conclusion regarding the pathogenesis of the diabetes mellitus which we have shown to be a rare but definitely noncoincidental occurrence in Friedreich's ataxia. We believe that cases such as the ones described in this article do serve as a basis for hesitation before accepting the "dia-

betogenic" action of the hypophysis as an explanation for the origin of the clinical entity, diabetes mellitus. These cases also serve to direct our attention to those portions of the central nervous system which regulate certain functions of the autonomic nervous system and to re-examine the evidence which may support the hypothesis of a reciprocally interacting neuroendocrine mechanism. It is hoped that our report may be of some interest, more especially to those who are engaged in the investigation of the neurogenic aspect of diabetes mellitus.

Summary and Conclusions

There are described the clinical records of two sisters who have developed diabetes mellitus during the course of a specific neurologic disorder, Friedreich's ataxia. Besides various extraneural anomalies these patients show evidence of endocrine dysfunction in the form of hypopituitarism, hypothyroidism, and hypogonadism.

A review of the literature discloses that the unusual concurrence of diabetes mellitus and Friedreich's ataxia has been reported previously in no less than 18 cases. Familial incidence has been noted four times affecting a total of 9 cases and, without exception, diabetes has been present only in siblings affected by Friedreich's ataxia while the reverse has not been true. In all instances the onset of the neurologic disorder antedates the onset of diabetes, usually by a period of many years.

Various pathogenic hypotheses for this disease combination are considered. Hereditary predisposition and neurogenic diabetes are thought to be the more likely hypotheses. They are discussed as to their relative merits and their correlation with clinicopathologic and experimental data. It is felt that these cases serve as a warning against hasty acceptance of the pathogenic concept for diabetes mellitus which is based on the "diabetogenic" action of the hypophysis.

This investigation seems to indicate that the extent of involvement of the central nervous system in Friedreich's

ataxia is considerably greater than ordinarily considered. The importance of making complete neuropathologic examinations in this neurologic disorder is emphasized.

Since Friedreich's ataxia constitutes a clinicopathologic entity while in diabetes mellitus a definitive pathology as yet has not been discovered, it would appear that a careful study of cases such as the ones described herein may aid in elucidating the pathogenesis of diabetes mellitus.

IS THIS SELFISHNESS?

"I am not an oldster, but I recall the days of Lydia Pinkham, electric belts, the traveling advertising quack, and the Indian medicine show. I recall the time when the existence of most medical journals depended on the advertising of worthless proprietary preparations and apparatus. I remember the slander suits brought against the officers of the Association because of its campaign against quackery and dishonest advertising, and the alarm felt a quarter of a century ago because of the plague of cult practitioners seeking a short cut to care for the sick. In defense of scientific medicine, we were then, as now, accused of being a high-handed monopoly. I recall the efforts required to develop

and perfect our public health service and our laws relating to license for the practice of medicine. There was determined opposition at every turn.

"Is all this the story of a group indifferent to human need? Is this a story of selfishness? Were these benefits for the physician? Or has there been enacted the drama of an idealistic profession fighting to wipe out the diseases which furnish it a livelihood, battling to protect its people against fraud and striving at all times to defend the advancement of science, and honesty in its application?"—*Rock Sleyster, M.D., President of the A. M. A., addressing the New Hampshire Medical Society*

TO CURE EVERYBODY BY LOTTERY

A constitutional amendment authorizing a state lottery to finance a long-range health program and provide for the free distribution of medicines was proposed in the legislature at Albany on January 17. The proposal was

dropped into the assembly bill hopper by Assemblyman Aaron Goldstein, Brooklyn democrat.

Along with this proposal Goldstein reintroduced his bill that was killed in the 1939 session to set up a system of free medicine.

MECHANICAL OBSTRUCTIONS OF THE SMALL INTESTINE

WILLIAM F. MACFEE, M.D., New York City

(From the Department of Surgery, New York Hospital and Cornell Medical College, and the Surgical Services of St. Luke's Hospital, New York City)

SINCE obstructions of the small intestine can occur in so many ways and under such a variety of circumstances, it is obviously necessary to specify the types which are to be considered. The present discussion, based in part upon a review of 328 cases, is limited to obstructions of the small intestine produced by conditions that mechanically interfere with the passage of its contents. Complete and incomplete simple obstructions and those associated with strangulation are included. Obstructions primarily caused by paralytic conditions, mesenteric thrombosis, and regional enteritis are omitted. By such restriction it is believed that confusion will be avoided.

Etiology

The causes of simple mechanical obstruction may, for convenience, be divided into conditions that act within the lumen of the bowel and those that obstruct from without.

Obstructions from within the bowel are relatively few. Occasionally a large gallstone finds its way into the duodenum by erosion and lodges in the small intestine. Fruit skins, bran, and other bulky substances occasionally become impacted in the terminal ileum^{1,2} or the lumen may be occluded at any point by a primary tumor.

Mechanical obstructions due to conditions outside the intestinal lumen are far more common. They are most frequently caused by adhesions resulting from an operation or an inflammatory process. Such adhesions produce obstruction by sharply angulating the bowel, by constricting it, or by forming a loop through which a coil of intestine passes and becomes engaged.

Obstruction due to angulation or con-

striction is the simplest type and produces anatomic and physiologic changes of the least immediate gravity. The first result of such an obstruction is an arrest of intestinal contents with gradual distention of the bowel.

Pathologic Anatomy and Physiology

Local—If a simple obstruction is not relieved, changes of a serious nature set in. There is a gradual accumulation of fecal matter, fluid, and gas proximal to the obstruction. Because of internal pressure the intestinal wall becomes stretched and thin, and the small collapsible veins and capillaries are compressed. There is a transudation of fluid elements from the blood vessels into the bowel wall, into the lumen of the bowel, and into the peritoneal cavity. The results are an edema and increased friability of the wall, an increase in the intraluminal fluid, and an accumulation of free fluid in the peritoneal cavity. Bacteria within the lumen multiply rapidly and toxic agents are elaborated. Distention gradually progresses until the nutrition of the intestinal wall is compromised, bacteria may pass through into the peritoneal cavity without actual perforation, or direct contamination may occur through gangrenous openings.

If an obstruction is complicated by strangulation, the changes described above go on much more rapidly in the strangulated loop than in the intestine proximal to it. The proximal segment of intestine is merely obstructed and its blood supply is not immediately compromised. The strangulated segment, on the other hand, suffers an immediate restriction of its circulation. Interference with the venous return leads to extensive interstitial hemorrhages (Fig. 1), and degenerative changes tend to occur

much earlier than in simple obstruction.

Among the first physiologic effects of obstruction are intermittent, painful intestinal contractions soon followed by vomiting. The intestinal contents below the obstruction are likely to be evacuated per rectum and after this no further passage of feces occurs. When the obstruction is complete gas does not escape. If the obstruction is not relieved, pain will continue as long as there is sufficient intestinal tone to produce peristalsis, and vomiting usually persists until the patient succumbs.

General—The general manifestations of simple obstruction are related chiefly to the effects of dehydration and intoxication. In strangulation the extravasation of blood into the bowel may be a matter of importance if the segment is long.³

Under normal conditions the secretions of the stomach and upper intestinal tract, gastric, pancreatic and enteric juices, and bile range from 2,000 cc to 10,000 cc per day.^{4,5} The greater part of this total, consisting chiefly of water and inorganic salts, is normally reabsorbed from the lower small intestine and colon and again takes part in the metabolic processes of the body. However, if an obstruction exists, the fluid which would ordinarily be reabsorbed is vomited and so lost to the body economy. Depletion proceeds at a rapid rate and the condition is further aggravated by inability of the patient to retain water or other fluids taken by mouth. The unchecked loss of water eventually leads to interference with urine excretion, with heat regulation, with the maintenance of normal blood volume, and with virtually all metabolic processes of the body.

The toxemia encountered in obstruction is associated more closely with strangulation than with simple obstruction. From the experimental work of numerous investigators it has been established that toxic materials are elaborated in a strangulated loop of intestine. The nature of the toxic agents and the mode of their absorption are not definitely known.

Substances which have been considered responsible⁶⁻¹⁴ are the various ptomaines, proteose, heteroproteose, toxic amines, and more recently, potassium histamine. Histamine has been demonstrated in the transudate from strangulated loops^{15, 16} but not in amounts sufficient to produce directly the profound depressor effects commonly observed in strangulation. The suggestion has been made that histamine and other poisons of acute obstruction give rise to harmful effects in an indirect manner.¹⁷ Their stimulating action on gastric secretions has been demonstrated^{18, 19} and any increase in the output of gastrointestinal secretions would necessarily lead to a greater loss of body fluids and electrolytes through vomiting.

Whatever the substance or substances may be, they have a depressor effect generally comparable to that of histamine and produce a shocklike state. Their activity is most strikingly demonstrated after the release of a long strangulated loop. The rather sudden return of circulation washes the accumulated toxic materials into the general circulation with depressing effects.²⁰ In obstruction with longstanding strangulation, three factors are at work, dehydration, toxic substances, and hemorrhage, all of which tend to reduce the volume of blood in circulation and thereby produce a state which is comparable to secondary surgical shock.

Symptoms and Signs

The symptoms of obstruction—cramp-like abdominal pain, nausea, vomiting, and inability to pass feces or gas, are too well known to warrant extended discussion.

The signs of obstruction—distention with tympany, visible peristalsis, borborygmus which is synchronous with intestinal cramps, vomiting, and later the signs of dehydration and shock—are likewise well known and when present the diagnosis ordinarily offers no great difficulty. The laboratory findings often fail to help and may be confusing. A roentgenogram of the abdomen, however,

FIG 1 Low and high power photomicrographs showing extravasation of blood in strangulated intestine.

is often a valuable aid²¹ since it reveals the distribution of distended coils of intestine and frequently indicates the approximate location of the obstruction. It is particularly valuable in demonstrating whether the obstruction is in the large or the small bowel.²² Distention of the colon with gas indicates that the lesion is in the colon, whereas a collapsed colon with distended loops of small intestine indicates an obstruction above the level of the ileocecal valve. Differentiation between lesions of the large and small intestines is a matter of considerable importance in planning treatment.

Differential Diagnosis

If the classic symptoms and signs of obstruction are present and there is an abdominal scar or an irreducible hernia, the diagnosis is relatively easy. Diagnostic errors in the presence of typical symptoms, however, are occasionally made, such errors are usually due to co-existing disorders which mask or confuse the picture, or to an inexplicable lapse of human judgment. There are, however, certain conditions under which the diagnosis or exclusion of obstruction may be difficult.

A common circumstance in which diagnosis may be troublesome is in the persistence of distention and vomiting after an abdominal operation. A continuation of these symptoms beyond the usual period suggests the possibility of peritonitis, obstruction, a functional disturbance, or a combination of such conditions. In the case of peritonitis such basic signs as temperature, pulse, respirations, and leukocyte count tend toward a higher level than in simple obstruction. Temperature and leukocyte count are often high in strangulated obstructions,²³ but early postoperative obstructions are not often associated with strangulation.²⁴ The pain in peritonitis shows less tendency to be cramplike and is not so regularly associated with borborygmus. The obstipation in peritonitis is not complete and enemas will ordinarily yield some feces and gas. In diffuse peritonitis an x-ray examination of the abdomen shows

a more or less uniform distention of the whole intestine including the colon. In obstruction, the intestine distal to the point of occlusion is collapsed.

Lesions or operations affecting the kidney or ureter sometimes give rise to abdominal pain and distention of marked severity and duration. Other conditions which may present confusing symptoms are acute hemorrhagic pancreatitis, gallstone colic, lead colic, tabetic crisis, perforated peptic ulcer, acute appendicitis, allergic conditions affecting the intestinal tract, and diaphragmatic pleurisy. A discussion of the differentiation of all these conditions obviously cannot be undertaken.

Treatment

The ideal treatment of intestinal obstruction is surgical removal of the cause provided the condition of the patient and his surroundings permit such an undertaking. Poor condition of the patient or lack of proper equipment and personnel may force delay. Under such circumstances restorative measures should be applied until operation becomes possible.

Nonsurgical Treatment

- 1 Parenteral fluids
- 2 Gastrointestinal drainage by duodenal tube.

3 Enemas

Parenteral Fluids—The fluid to be employed intravenously or by hypodermoclysis is *physiologic* salt solution in large amounts. For the average adult not less than 2,000 cc. of normal saline should be given intravenously at the outset, and this should be supplemented until the total amount given in twenty-four hours is not less than 50 cc per kilogram of body weight, ordinarily about 3,500 cc. The quantity suggested will not do more than fulfil normal water requirements²⁵ and should be regarded as the basic dose. In obstruction of several hours' duration there is an important depletion of body fluids, mainly through vomiting, and to compensate for this loss an equivalent amount of salt solution should be added to the basic dose.

In prolonged vomiting, especially in high obstruction, there is a loss of sodium base and chloride in addition to the loss of water. Investigations²⁶⁻³¹ have shown that sodium and chloride ions, particularly the sodium ions, are intimately concerned in the ability of the body to retain water and, by corollary, a normal blood volume. The beneficial effects of the administration of large amounts of sodium chloride solution in intestinal obstruction were reported in 1912³² and have been confirmed in subsequent studies³³⁻³⁶. A physiologically normal solution should be used. Higher concentrations tend to extract water from tissues which are already depleted, and the temporary hydraemia may lead to an actual loss of water through kidney excretion. The same may be said of hypertonic glucose. In isotonic solution, 5 per cent, glucose is valuable, partly on account of its own nutritive value but mainly because it aids in the metabolism of body fat. The average tolerance for glucose given intravenously is said to be 0.85 Gm per kilogram of body weight per hour.³⁷

The transfusion of blood is indicated in simple obstruction of long duration and in strangulation. In simple obstruction blood plasma is lost by transudation, and in strangulation there is sometimes a considerable loss of red cells as well as plasma.

Gastrointestinal Drainage—Drainage of the regurgitated fluid which collects in the stomach and upper intestinal tract is made relatively easy by means of the gastric catheter,³⁸ introduced preferably by way of the nostril. The beneficial effects are due to relief of distention with improvement of intestinal circulation, to the rest which it affords the patient, and possibly to the removal of some toxic agent contained in the regurgitated intestinal fluid.^{39, 40}

Drainage through the tube may be accomplished by intermittent aspiration and lavage or by continuous suction.⁴⁰ In either case it is important to attend to replacement of fluid and electrolytes by the parenteral administration of normal saline.⁴¹

The Miller-Abbott tube is an admirable device for gastrointestinal drainage.⁴²⁻⁴⁴ With this tube it is often possible to drain completely and continuously the segment of intestine lying proximal to the point of obstruction and immediate operation is made unnecessary. It often requires considerable patience and skill to secure passage of the tube beyond the pylorus, and when efforts are not successful within a reasonable time operation should be undertaken without further delay.

Enemas—In the attempt to relieve obstruction by nonsurgical means the enema has been resorted to more consistently than any other procedure. In mechanical obstruction, however, it is doubtful whether the enema has any real value beyond helping to establish the diagnosis. It is not likely that it can do more than empty the bowel below the site of obstruction and stimulate peristalsis. Peristalsis is usually active without artificial stimulation and excessive motility may constitute a danger. Protracted attempts to relieve obstruction by means of enemas have undoubtedly contributed materially to the high mortality in this disease.

Surgical Treatment

The effective relief of obstruction depends ultimately upon a direct removal of the cause. Conditions being favorable, operation should be undertaken at the earliest possible moment. If, however, the patient gives evidence of marked dehydration and is in a shocklike state, he should have a period of gastrointestinal drainage and fluid replacement before operation is undertaken.

Incision—If there is no definite indication as to the location of obstruction, a right rectus incision made near the midline will frequently prove satisfactory. The majority of obstructions of the small intestine are in the distal portion of the ileum.

Procedure—An immediate inspection of the ileocecal region will often lead to discovery of the obstruction. If collapsed, the terminal ileum sometimes can be followed retrogradely to the obstruct-

ing lesion. Adhesions frequently make this approach impracticable and it becomes necessary to seek the point of obstruction by following the distended intestine from above downward. The obstructing mechanism is usually single, and the division of adhesions which have no part in the obstruction is useless and may well lead to disastrous perforations of the friable gut.

Viability of Strangulated Loop—When strangulation complicates obstruction the best indications of viability of the strangulated loop are preservation of the glistening appearance of the serous surface, definite improvement in color upon release, return of lifelike consistency as contrasted with the flaccidity of necrotic gut, and peristalsis or other evidence of contractility when warm salt solution is applied. If there is doubt, it is, perhaps, safer to resect the strangulated loop.⁴⁵ When the loop is definitely gangrenous, the necrotic portion is resected with a good margin and continuity is restored by anastomosis. In desperate cases the loop may be exteriorized with an enterostomy tube placed in its proximal lumb

Enterostomy

1 *As a Primary Procedure*—For several years the impression has been widespread that the safest operation in acute obstruction is an enterostomy, with little or no attempt to determine the cause of obstruction. If by chance a strangulation is present, the result of simple enterostomy will be almost inevitably fatal. An enterostomy performed above the level of a strangulation does little to relieve the strangulated loop which goes on to gangrene and perforation. An enterostomy may be done in such a case without discovering that strangulation exists (Fig 2). The distended bowel above the site of strangulation presents all the characteristics of a simple obstruction. Strangulation should always be suspected if there is bloody fluid in the peritoneal cavity.

The safety of simple enterostomy as a surgical measure has also been wrongly emphasized. Local or general peritonitis,

wound infection, failure to relieve obstruction, and digestion of the abdominal wall are not at all uncommon complications of this procedure. If the enterostomy is placed high, in the upper jejunum for example, there is often leakage about the tube with digestion of the surrounding abdominal wall. The opening becomes progressively larger and quantities of water and chemical substances essential to survival of the patient are lost. These can be restored only in part by artificial means and unless the loss can be checked a fatal outcome is likely. The deleterious effects of high intestinal fistulas have been amply demonstrated experimentally⁴⁶⁻⁵⁰ and are well known clinically.

2 *As a Secondary Procedure*—After the cause of a simple obstruction has been found and the condition rectified, nothing more, as a rule, should be done. There is no logical reason why the addition of an enterostomy should improve matters. When released from the obstructing mechanism the bowel can evacuate its contents into the segment lying distal to the point of occlusion quite as readily as through an enterostomy tube, and there is no evidence that toxic contents are absorbed from normal mucosa.⁵¹⁻⁵²⁻⁵³ From statistical studies it appears that enterostomy after the obstruction has been relieved not only is useless but actually increases the mortality.⁵³⁻⁵⁶⁻⁵⁴

Postoperative Complications

In the simple cases of short duration the postoperative complications are likely to be few and of a kind that might follow any operation. If the obstruction has been of long duration additional dangers present themselves.

1 Because of the great loss of fluid and toxemia, particularly if there has been strangulation, the patient may pass into a shocklike state and succumb even though relief of the obstruction has been perfectly executed.

2 Another grave complication is peritonitis which may develop with or without intestinal necrosis, or from injury to the intestine during operation.

3 In cases with marked obesity, multiple adhesions, great distention, or other surgical handicaps there is the possibility of failure to identify the cause of obstruction. A hidden band or a strangulated loop may have been overlooked.

4 Occasionally, when the bowel has been distended or strangulated for a long time there is a delay in recovery of tone, and paralytic ileus may supersede a mechanical ileus.

5 Complications such as heart failure and urinary suppression are most often due to no basic fault of the organs concerned but are manifestations of a lack of sufficient fluid to provide blood volume and urinary output.

Postoperative Treatment

1 First of all the patient's stomach should be emptied immediately after operation to prevent the aspiration of vomitus during the period of unconsciousness.

2 Gastroduodenal drainage should be continued until it is evident from the character of the fluid obtained, from the disappearance of distention, and from the evacuation per rectum of feces or gas that normal intestinal activity has returned.

3 Continuation of intravenous saline therapy is most important. Fluid should be given in amounts sufficient to maintain a water balance with enough glucose added to prevent ketosis. There need be no immediate anxiety concerning food.

4 Repeated enemas and drugs intended to promote peristalsis are usually uncalled for. As a rule the decompressed intestine quickly recovers tone and regains its normal motility. Until the intestine is capable of response, purgatives can do no good and they may be harmful. The effects of morphine on the small intestine are not completely established^{17,18} but there appears to be no definite contraindication to its use for relief of pain.

5 Fluid by mouth should be restricted to water until it becomes evident that nourishing fluids will be tolerated.

6 Treatment of organic postoperative

FIG 2 Sketch indicating the futility of enterostomy above an undiscovered strangulation. An opening in the obstructed proximal intestine does not relieve the strangulated loop.

complications will be indicated by the nature of the disorder. It should be remembered that the majority of cardiac and urinary disturbances are the result of fluid deficiency, and stimulating drugs are not indicated.

Mortality

In the present study special attention was given to mortality in relation to type and cause of obstruction. There was also an attempt to correlate mortality with the operative procedure. The kind of obstruction, the type of operation, and the associated mortality are indicated in the tables.

The total number of deaths in the 328 cases of partial and complete obstruction was 80, or 24.4 per cent. The number of cases of complete simple obstruction was 108, with 37 deaths, a mortality of 34 per cent (Table 1). Complete obstruction associated with strangulation was present in 106 cases, with 34 deaths, a mortality of 32 per cent (Table 2). The incomplete or partial obstructions numbered 114, with 9 deaths, a mortality of 8 per cent (Table 3).

The mortality associated with the various operative procedures is also shown in the tables. It will be observed in general that release of the obstruction by the simplest means gave the lowest mortality. In the 214 complete obstructions, simple and strangulated (Tables 1 and 2), the general mortality was 33.2 per cent, this includes those who had only an exploration and those who died without operation. In 150 cases of the two groups the cause of obstruction was surgically removed *without the addition of enterostomy*, the mortality in this series was 19, or 12.7 per cent. In 26 cases of the same groups the cause of obstruction was surgically removed *with the addition of enterostomy*, the mortality following the double procedure was 16, or 61.5 per cent. The causes of death following enterostomy were peritonitis or wound infection, 10 cases, secondary shock, 3 cases, cardiac failure (auricular fibrillation), 1 case, death on the operating table, 1 case, obstruction not relieved, 1 case.

It may be taken for granted that the 26 cases subjected to enterostomy were regarded as the more serious ones but the reason for enterostomy was not often clear. Presumably it was considered a safety measure.

Enterostomy alone in 15 cases of complete simple obstruction showed a mortality of 53 per cent. In 5 cases of complete obstruction due to strangulation enterostomy alone yielded a mortality of 100 per cent

Causes of Death

A review of the 80 deaths occurring in the entire series revealed the following causes

Metastatic carcinoma 15 cases Although not all obstructions and not all deaths in this group were directly due to carcinoma, it seems fair to group them together

General peritonitis 13 cases In 8 of these enterostomy had been performed either alone or as a part of the procedure, in 1 case a resection had been done, in 1 case there had been an accidental rup-

ture of the intestine, and in 3 there had been no operation, or merely an exploration

Persistence of obstruction 12 cases
In 5 of these enterostomy had been performed above the site of a strangulation, in another case ineffective lysis of adhesions had been done, in 1 of simple obstruction enterostomy was done, in 4 no operation or merely an exploration had been done. The futility of simple enterostomy in the presence of strangulation has been indicated (Fig 2 and Table 2)

Intoxication, dehydration, or shock 10 cases

Cardiac decompensation 7 cases

Local peritonitis or wound infection 6 cases
In 2 of these enterostomy alone had been performed and in the remaining 4 it was a part of the procedure

Pneumonia 3 cases

Pulmonary embolus 1 case

Inhalation of vomitus while still under anesthesia 1 case

Death on table from spinal anesthesia 1 case

Death on table from shock 1 case

Paralytic ileus following release of mechanical obstruction 1 case.

Suppression of urine 1 case.

Cause of death not definitely determined 8 cases

General Prognosis

The prognosis is largely an individual matter and depends much upon the duration and nature of the obstruction. It depends no less upon rational therapy. Liberal use of parenteral fluids and gastrointestinal drainage will increase the salvage of life in late cases.

The age of the patient is also a matter of importance. The mortality is generally higher in the first years of life and in the years past middle life.^{59,60} Survival, however, depends less upon age than upon conditions more intimately associated with the obstruction. Rational treatment should never be withheld because the patient happens to be old.

The prognosis with respect to future attacks can hardly be estimated. In this series, however, 67 per cent of the patients had had one or more previous operations for obstruction. It appears, therefore, that the probability of obstruction is much greater in those who have had previous attacks.

Summary

In this series the most common etiological factor in the production of simple mechanical obstruction, both complete and incomplete, was old postoperative adhesions. They accounted for 56 per cent of the complete obstructions and 49 per cent of the incomplete obstructions. The factor of next greatest importance in simple obstruction was the formation of adhesions during the course of convalescence from another operation. Eighteen, or 17 per cent, of the complete simple obstructions and 15, or 13 per cent, of the incomplete obstructions were caused in this way.

Adhesions without a history of previous operation were responsible for partial or complete simple obstruction in only 8 of 214 cases, 3.7 per cent.

In the complete obstructions with strangulation, old postoperative adhesions were responsible for 14 of 106 cases, or 13 per cent. There was no case of strangulation from recent postoperative adhesions. The majority of the strangulated obstructions, 63 per cent, were caused by hernias.

Conclusions

The treatment of intestinal obstruction consists primarily in operative attack upon the obstructing lesion. Gastrointestinal drainage by means of a suitable catheter and the parenteral administration of large amounts of fluid are valuable preoperative and postoperative adjuncts.

Enterostomy after an obstruction has been relieved is uncalled for and actually appears to increase the mortality. Its use should be reserved for those cases in which the condition of the patient does not permit a more extended procedure.

MYSTERY OF THE VACANT CHAIRS

"I cannot understand why so few men attend their county and state medical society meetings. It is not because they are so busy, as the busiest physicians are always found where there is a chance to learn. After years of observation I have reached the conclusion that there are three kinds of physicians who don't attend meetings—(1) the person who has not the ability to plan his work so that he can have an evening for recreation at the meeting, (2) the man who thinks he knows it all, has not read a new book since leaving school, and has no time for reading the *Journal* or other publications, and (3) the man who is afraid he might lose a patient should he

leave his office. These three types form the fault-finding group, they complain, but will not come to the meetings and put their shoulders to the wheel, clarify their visions, help remove the faults they see, and become what is most needed by the society and always welcomed by its officers—workers instead of drones or complainers.

'Yes, the opportunity for the present day physician to be an up to date physician is right at his door, and I am not only sorry for those who are missing these opportunities, but for their patients.'—John A. Hawkins M.D., *Pitts burgh Medical Bulletin*

Four outbreaks of food poisoning have been traced to one bakery in Troy, New York, in the past four years, according to the State Department of Health, all due to chocolate eclairs, straw-

berry cream pie, and coconut cream pie. The latest was in November. Newspaper and radio warnings against eating cream filled pastries made by this bakery have been issued.

TRAUMA IN RELATION TO PULMONARY TUBERCULOSIS

CHARLES EDWARD HAMILTON, M D , Brooklyn, New York

(Director, Tuberculosis Division, Kings County Hospital)

OUR present concept of the evolution of pulmonary tuberculosis holds that we are dealing with a disease that commences with a primary infection stage, occurring in most instances in the lungs although it may arise in the intestines, skin, tonsils, or elsewhere in the body, enters a second stage of generalization through the blood stream, and finally a tertiary stage of localization in the lungs, or phthisis

Once the infection occurs within the body its future course is subject to many variations. It may heal completely, remain latent and dormant for years, spread slowly and progressively or rapidly and in fulminating fashion, or have longer or shorter periods of arrest of the process followed by exacerbations of renewed activity, pursuing in this manner a period extending from a few weeks to many years before terminating in the death of the patient

The factors of inherited resistance, allergy, and immunity all exert a determining influence on this course of the disease, but they, too, are variable factors, being at one time at a high level of protective efficiency and later at a very low level or wholly unprotective. At present these factors are imponderables, we cannot measure their protective value or, with allergy, their potentially destructive value

However, we feel that there are certain known conditions that influence these states for better or worse, thereby determining the course that the disease will follow. Among these conditions may be mentioned the race, sex, and age of the patient, his social and economic status, lack of rest and fatigue, enfeeblement of the body from exposure or sickness, excessive physical or mental strain,

and trauma. No one of these conditions is the cause of pulmonary tuberculosis, but through disturbing the bodily defenses they exert an influence to reactivate an existing lesion. So, as a foundation for our consideration of the subject of trauma in relation to pulmonary tuberculosis we must predicate that trauma cannot cause tuberculosis. Tubercle bacillus infection of the lung must be present to cause the disease. Trauma, along with other factors, may then influence the course that the disease follows

Active pulmonary tuberculosis arising directly from a primary tuberculous infection induced by trauma is extremely rare. The Jewish ritual of circumcision performed by a tuberculous rabbi would be an illustration of such a possibility, and such cases have been reported. However, this is followed by generalized military tuberculosis, not pulmonary tuberculosis per se. It is conceivable that a sharp instrument, contaminated with tubercle bacilli, penetrating the chest wall and perforating the lung might cause a primary infection of the lung. Such an occurrence would be most exceptional

Our interest, therefore, is restricted to the potentiality of active tuberculous disease resulting from trauma-affecting foci existing in the lungs at the time of traumatization

It is generally felt more difficult to judge the role of trauma in pulmonary tuberculosis than in tuberculous involvement of any other system of the body, and the literature abounds with contradictory statements and opinions of experts in this work. We must appreciate that the expert's opinion is often only presumptive, based on his experience and judgment, and sometimes merely

possible in the individual case Schullerth¹ states "In speaking of the course and aggravation of any case of pulmonary tuberculosis, outside influences should never be held responsible, but the force of the existing disease itself must be considered. One can hardly fix the blame on any one factor."

Sante² states "Surely we must admit that trauma certainly does not play more than a very minor part in the development of pulmonary tuberculosis. Trauma, alone, as an etiologic factor in its development is highly speculative, though it is logical to suppose that trauma severe enough to cause actual injury to the lung might disturb the bodily defenses against a pre-existing tuberculous lesion by removing the fibrous tissue barrier and permitting advancement of the disease."

Amberson³ states "Knowing as we do that the course of pulmonary tuberculosis is subject to many deviations, it often becomes an exacting task to distinguish the developments which are due to trauma from those which merely follow trauma. In some instances the question is a matter of judgment, which varies with the experience and conceptions of the clinician, but in a majority of cases it is possible to obtain objective evidence which is of definite and decisive value."

Howes⁴ states "The causes of relapse in pulmonary tuberculosis are numerous including the effects of accidents and injuries."

Krause⁵ says "It is generally conceded that trauma sets up active pulmonary and regional lymph-node tuberculosis as well as pleuritis and several other major diseases, whose causation is primarily conditioned by the presence in the lungs of tuberculous foci, active and appreciated or inactive and unsuspected, at the time of trauma. This is the common and ordinary way that pulmonary tuberculosis is affected by trauma. It presupposes that tubercle of the lungs exists before and at the time of traumatization, and that if it has never before been clinically manifest or active,

trauma induces activity, or that if mildly active, its existence may not have been suspected by patient or physician until some trauma brings active tuberculosis plainly to the foreground, or that if active in the past, the disease is in a state of clinical arrest at the time of trauma which again reactivates it."

Granting the difficulty of passing judgment on the effect of trauma in the individual case, I cannot but feel its causal relationship in many cases of tuberculous reactivation or extension. Our aim must be to try to estimate this relationship in terms of known fact and not theoretic hypothesis.

The potentialities of trauma may be direct or indirect. That is to say, we may have an injury to the chest wall followed immediately or after a varying interval of time by pulmonary tuberculosis, or we may have an injury to some other part of the body, not involving the chest, followed by prolonged debilitating illness lowering the patient's resistance and reactivating a quiescent or undetected tuberculous focus into clinically active disease abruptly or gradually. The abrupt manifestation of tuberculosis following trauma is heralded by hemoptysis or spontaneous pneumothorax due to the mechanical effect of the trauma. Unquestionably, the majority of cases of pulmonary tuberculosis develop activity despite any trauma, and most hemoptyses and spontaneous pneumothoraces occur when the patient is relatively quiet. When these developments occur shortly following trauma, one can scarcely dispute the causal relationship, especially when manifest tuberculosis is found within the lungs and with our knowledge of how soft and friable such diseased tissue is compared with healthy lung tissue.

Greater difficulty is encountered when the onset following trauma is more gradual and ushered in with constitutional symptoms, i. e., malaise, fatigue, fever, loss of weight, etc.

Trauma as it affects the lungs may result from (1) penetrating wounds of the thorax, (2) blows on the chest or

crushing or squeezing injuries, (3) fractures of the bony thoracic cage, (4) sudden changes of atmospheric pressure or weather, (5) inhalation or aspiration of foreign matter

Penetrating wounds of the chest are rarely followed by pulmonary tuberculosis. Frischliuer⁶ studied 6,000 tuberculous soldiers among whom there was only 0.77 per cent reactivation of the tuberculosis by gunshot wounds of the chest. Letzerer⁶ believes the reactivation depends upon whether the bullet penetrates the tuberculous focus or not, obviously a chance occurrence.

The most common type of trauma inducing reactivation of pulmonary tuberculosis is that caused by blows to the chest or crushing or squeezing injuries with fracture of the bones of the thorax. The force of the blow undoubtedly is a determining influence on the subsequent result, as is the question of where the blow strikes. It is hard to conceive of a blow on the left lower chest adversely affecting a right upper-lobe lesion. Yet both of these influences present imponderable aspects and are subject to varied interpretation.

The late Dr. Herman Biggs felt that percussion of the chest could traumatize the tuberculous lung. Many of us feel that the physical examination of the lungs with deep breathing and cough is not a beneficial influence on tuberculous lungs. Yet, a tunnel worker, a former tuberculous patient with a thoracoplasty on one side, in a mishap with compressed air was blown forcibly, landed with his opposite side against a heavy beam fracturing four ribs, but suffered no subsequent activation of his tuberculosis.

The character of the disease process in the lung must also be considered in its relationship to trauma. The soft caseating or cavitating lesions, or the fresh inflammatory lesions which are progressive or on the verge of progression, are more susceptible to the adverse influence of trauma than the latent calcified or fibrotic lesions.

The influence of sudden changes in atmospheric pressure or inclemency of

the weather is illustrated in the following cases. A diver whose breather line is blocked is rapidly hauled up and resuscitated. Shortly thereafter he has a hemoptysis. The following week he complains of languor and malaise with slight fever and cough ensuing. Six weeks after his accident x-ray reveals tuberculosis of his right lung. Or the fireman, fighting a bad fire on a cold winter day, is thoroughly drenched with water and frozen completely so that later he has to be thawed out. This is followed by a "cold" with subsequent malaise and fatigue. Three months after this episode it is diagnosed as a case of pulmonary tuberculosis.

The inhalation or aspiration of foreign matter into the lungs as a factor in causing tuberculosis is well known to all and well illustrated by the silicotuberculosis of stone cutters. Less understood as a harmful influence is the inhalation of various gases. These undoubtedly cause edema and congestion of the bronchial mucosa and alveolar cells, giving rise to bronchitis and bronchopneumonia. With subsequent lowering of the patient's resistance it is possible that tuberculosis may develop. There is no agreement on this point, however. Hager⁶ states that during the War tuberculosis was far less frequent than a form of chronic bronchitis as a consequence of gas attacks. Experimental work on rabbits exposed to various gases seems to indicate that the exposed animals are more resistant to tuberculosis than the unexposed animals. Von Steinmeyer⁶ found in 2,284 cases of pulmonary tuberculosis in war veterans that 4.9 per cent had suffered gas poisoning. Generally, it is estimated that 2-3 per cent of those exposed to gas in the War developed tuberculosis later. Weimart and Minkowski⁶ feel that carbon monoxide has more of a predisposing influence on the development of tuberculosis than other gases.

Another question involved in this problem is: How much time can elapse following trauma before its effect on the lungs manifests itself? This, too, is a perplexing problem to ponder.

possible in the individual case Schulerth¹ states "In speaking of the course and aggravation of any case of pulmonary tuberculosis, outside influences should never be held responsible, but the force of the existing disease itself must be considered. One can hardly fix the blame on any one factor."

Sante² states "Surely we must admit that trauma certainly does not play more than a very minor part in the development of pulmonary tuberculosis. Trauma, alone, as an etiologic factor in its development is highly speculative, though it is logical to suppose that trauma severe enough to cause actual injury to the lung might disturb the bodily defenses against a pre-existing tuberculous lesion by removing the fibrous tissue barrier and permitting advancement of the disease."

Amberson³ states "Knowing as we do that the course of pulmonary tuberculosis is subject to many deviations, it often becomes an exacting task to distinguish the developments which are due to trauma from those which merely follow trauma. In some instances the question is a matter of judgment, which varies with the experience and conceptions of the clinician, but in a majority of cases it is possible to obtain objective evidence which is of definite and decisive value."

Howes⁴ states "The causes of relapse in pulmonary tuberculosis are numerous including the effects of accidents and injuries."

Krause⁵ says "It is generally conceded that trauma sets up active pulmonary and regional lymph-node tuberculosis as well as pleuritis and several other major diseases, whose causation is primarily conditioned by the presence in the lungs of tuberculous foci, active and appreciated or inactive and unsuspected, at the time of trauma. PRE-BUGGY MEDICINE—THE HORSEBACK DOCTOR

I have a personal knowledge of rural medicine extending beyond seventy years. At first, my father's only means of transportation was horseback, for a horse was quicker than a wagon and could go any place a man could go, and the horse rarely mired down.

There was a bond in those days between the patient and doctor that had a definite effect on the outcome of the case. One of the family went on horseback to fetch the doctor. The case was usually serious, for there was no telephone to call the doctor out of bed to see someone who was more worried than ill. Galloping hoofs and the snorting of a hard-running horse usually awakened the doctor before the call came "Ho, Doc! Ho, Doc! Hello, hello!" This was followed by pounding on the door of the white house located on the corner opposite the store in Union Village. If it was winter, Dad crawled out of the warm feather bed and, without waiting to put on shoes crossed the cold hall, and opened the east door.

"Ma's going to have a baby, Doc," was usually the message. Sometimes it was "the baby's got the croup" or "Grandpap's taken bad." No matter what the call, Dad went. To fetch a doctor meant to go after him and bring him back. It was usually a serious case and Dad stayed as long as he was needed, perhaps all night. A close bond existed between doctor and patient under such conditions and the faith in the country doctor came somehow very near to faith in God. They might pray for God to save the baby, but it was from the doctor that the miracle was expected and often came.

A daytime call often lasted into the night. I have heard my English mother get up and go to the kitchen when she heard horse's hoofs in the barnyard. She opened the drafts to the stove, and rattled the lids as she tried to get the fire roaring to make Dad something hot to drink and thaw him out. I have seen her help him out of his overcoat and stand it behind the stove—the coat so frozen that it would stand by itself until the warmth of the stove melted it into a crumpled heap of steaming wool which could then be hung up to dry. Dad always looked after his horse before he took care of himself, for it was on the horse that he depended for his transportation.

An unbelievable change has come to the practice of medicine since my father saddled his horse and flung the saddle bags on behind him and made his lone way to his patient. The doctor of today still has a hick bag in which are a few emergency medicines, but in it also are the stethoscope, the sphygmomanometer, the otoscope, the ophthalmoscope, and other things used as aids in arriving at a diagnosis. Where my father practiced alone, the modern doctor of today knows that he has the city hospital with all its equipment at his call if he needs it, but the place of the general practitioner in the small city or rural community is still as important as ever because it is upon him that the responsibility falls for the proper diagnosis and treatment, or for referring to others for treatment, the persons who are sick in his locality.—O A Province, M.D., in the *Journal of the Indiana State Medical Association*

A BACK-ACTION CURE FOR STOMACHACHE

The Attorney-General of Minnesota, Mr J A A Burnquist, in a recent address before the Minnesota State Medical Association told of a clever reply of a doctor on the witness stand in St. Paul some years ago. The Attorney-General first remarked that the manner in which some of our people can be deceived through quacks and swindlers of every kind and description is remarkable. It is claimed that it costs this country through the expense of all of its law enforcing agencies and the loss of property and life through fraud and crime approximately \$15 000,000,000 annually.

In speaking of the pretenders to medical skill, he remembered an incident in an action against one of them tried some years ago in the court house in the city of St. Paul. The defendant, who had become widely known as a

healer and who resided at Somerset, Wisconsin, had been sued in Ramsey County for \$25 000 by one of his patients because of an infection resulting from the application of a plaster to his back, the only remedy that the alleged doctor ever applied. The health commissioner of St. Paul was on the witness stand. He was asked by the attorney for the plaintiff the following question "Suppose," he said "a man has stomach trouble and he consults the defendant, who applies to his back a plaster consisting of turpentine, aloes, and other ingredients. Is that of any benefit to the stomach?" The doctor on the witness stand delayed his answer momentarily and then said, "Yes I think it would be of some benefit. The patient's back would pain him so much that he would forget all about his stomach."

After the World War, disability was allowed ex-service men for tuberculosis if it developed six months after discharge from the service. This time was gradually extended until it finally applied to cases developing tuberculosis eight or nine years after discharge from the service, thus showing the difficulty the service doctors had meeting this problem. Ornstein and Ulmar⁷ feel that the disease must become manifest within two weeks following trauma to prove causative relationship. Lewy⁸ states that the time lapsing between trauma and the development of tuberculosis must not exceed six months. Mayer⁹ states that it may take months for tuberculosis to become manifest following trauma. Hager⁶ states the usual interval is six months with a maximum period of twelve months. Krause⁶ states "that with increasing experience, the open mind is bound to become more and more convinced that, as regards the possibilities of etiological factors in tuberculosis, there is no time element that can be fixed. A man may suffer an injury at almost any place in the body upon which some pulmonary disease may assert itself coincidentally or within a few days afterward or perhaps not until weeks, months, or even years following the injury." This will serve to show the wide variation of opinion on this question. I am inclined to feel that the development of tuberculosis later than two years following trauma would be open to a degree of skepticism.

Are there any protective measures that can be instituted against this hazard? Unfortunately, we can find but little help in this direction although we are not utterly helpless. An immediate roentgenogram of the chest of any person sustaining a chest injury would be highly desirable. If negative for disease, it will show the character and progress of any subsequent disease following trauma, enabling us to estimate the influence of this factor. Of course, we all must realize that a negative roentgenogram does not completely exclude the presence of disease. Studies have shown that 1 in every 6 persons dying of ailments other

than tuberculosis have caseating tuberculous foci in the lungs, and of these cases only about 40 per cent were detected by roentgen examination.

Should the roentgenogram reveal disease when taken, its course can be followed, subsequently, by serial pictures to determine any change in the lesion and whether it was a normal progress of the lesion as expected or one aggravated by the trauma. In cases of injury without chest involvement but where a long period of convalescence is anticipated or debilitating complications ensue, take a prophylactic roentgenogram of the chest for future reference if needed.

See that adequate and skilled care is given to every injured individual to minimize complications and prevent prolonged debilitating convalescence.

Think carefully of the problem of inhalation anesthetics in patients severely shocked after trauma.

Finally, consider the state of health of the patient at the time of trauma. Was he undernourished, suffering with diabetes, syphilis, arteriosclerosis, etc., at the time of injury—debilitating ailments rendering any trauma an extra health hazard? Had he recently recovered from any infectious disease or operation? Was he overfatigued, under the influence of alcohol? Answering these questions will aid greatly in judging the influence of trauma in the individual case.
